ADDRESSES AND ORIGINAL ARTICLES

THE INCIDENCE MORTALITY, AND TREATMENT OF HÆMORRHAGE IN GASTRIC AND DUODENAL ULCER

By Arthur F Hurst D M Oxon F R C P Lond
SENIOR PHYSICIAN TO GUY'S HOSPITAL, LONDON AND

J A Ryle M D F R C P Lond.
CONSULTING PHYSICIAN TO GUY'S HOSPITAL AND REGIUS PROFESSOR OF PHYSIC IN THE UNIVERSITY OF CAMBRIDGE

In spite of advancing knowledge in the fields of diagnosis and pathology we have evidence that peptic ulcer and its complications are becoming more rather than less frequent (Wilkie 1927 Ryle, 1932) Of the complications hæmorrhage is the commonest occurring at one time or another in approximately a third of all cases (Table I) If we except perforation it is also the most disturbing complication For these reasons but also because new measures of active treatment (Gordon Taylor 1935 Meulengracht 1935) have recently been advocated the whole subject of bleeding peptic ulcer may be considered ripe for review

Judgment in the face of a severe gastric or duodenal hæmorrhage must find its basis in pathological insight a sound knowledge of prognostic criteria and a just appreciation of therapeutic possibilities whether medical or surgical In the matter of the relative claims of medicine and surgery in the treatment of chronic ulcers uncomplicated by hæmorrhage we have always endeavoured to maintain a just balance of opinion For actively or recently bleeding ulcers we have almost always concluded in favour of *medical treatment*. Although we have retraced our steps for the purposes of this communication we see no reason to feel regret for past decisions Our reasons for conservatism backed by an analysis of our experience will follow but by way of introduction and as a reminder of practical difficulties two cases are described

The first case the only one in which J A R. has ever invited the cooperation of a surgical colleague was that of a man just past middle life who was known from clinical and X ray evidence to have a large ulcer on the lesser curvature who started to bleed profusely shortly after admission to hospital and whose hæmoglobin fell to 18 per cent. on more than one occasion transfusions of blood and the usual routine treatment notwithstanding The surgeon declined to operate and the patient made a complete recovery eventually losing his ulcer deformity

The second case was one of grave hæmorrhage also in a middle-aged man In this case medical treatment had been instituted with a completely satisfactory response but in spite of reasoned protests the patient was taken out of the hands of his doctor and J A R and operated upon No trace of an ulcer was found

These two cases exemplify three outstanding difficulties (1) the difficulty of giving a prognosis even when we know something of the nature site and size of the lesion and can gauge the amount and continuance of the blood loss (2) the difficulty of refraining from active interference because we possess this knowledge and because we are anxious; and (3) the difficulty in *many* instances of being sure whether there is a demonstrable ulcer present at all.

In the first case even if surgery after transfusion could have saved the patient's life it would have been a wrong decision for it would have added an undeniable risk, the necessity for which was disproved by the subsequent event. In the second case a quite unnecessary risk was actually taken with no benefit to the patient.

In a given case of sudden gastric or duodenal hæmorrhage having excluded such other causes as hepatic cirrhosis splenic anæmia cancer and the hæmorrhagic diathesis we are usually entitled to make a diagnosis of peptic ulcer the commonest *cause of bleeding from these sites* In *many* cases we can on the basis of history hazard a reasonable guess as to whether the bleeding comes from a recent or acute ulcer or from an old or chronic one Experience tells us that death very rarely results from recen ulcers that is to say in young subjects or in cas lacking a dyspeptic history Experience also tel us that in the great majority of cases of bleedin from chronic ulcers the immediate prognosis is goo however severe the bleeding There are howeve wide discrepancies in the mortality figures reporte in the literature, and as it is largely upon a ju estimate of risks that our choice between conservati treatment and more active forms of interventio must be based a new and careful study of progno must be allowed to precede all other considerations

In a long experience of post-mortem work we can recall only a small series of peptic ulcers fatal through bleeding In most of these there was a large posterior and often adherent ulcer with a big vessel opened in its base a type of lesion which must provide considerable difficulties for the surgeon even in an otherwise fit patient In the course of preparing a Hunterian lecture on duodenal ulcer in 1932 J A R found only 25 deaths from hæmorrhage from duodenal ulcer during twenty years at Guy's Hospital as compared with 128 deaths from other complications and sequels of this lesion In our private practice we have never seen reason to adopt a pessimistic attitude in the presence of these hæmorrhages and we find that most physicians of wide experience share this opinion

Incidence of Hæmorrhage in Chronic Ulcer

A full history was obtained from all the 580 cases of ulcer investigated in New Lodge Clinic between February 1921 and February 1936 and from the 751 cases seen in private practice by J A R from 1920 to 1935 so that the two groups form a fairly reliable basis for estimating the incidence of hæmorrhage The figures obtained though lower than those given by most observers are still probably too high as cases with mild or trivial symptoms are not likely to be sent to the Clinic or to be seen in

TABLE I

Incidence of Hæmorrhage in Duodenal Gastric, and Post operative Ulcers (A F H and J A. R 's private cases)

—	Total.	Number with hæmorrhage	Percentage with hæmorrhage
Gastric ulcer	211	79	3[illegible]
Duodenal ulcer	912	268	2[illegible] 4
Post-operative ulcer	1[illegible]	72	40 3
Total	1310	419	31 3

consultation, so that the proportion with severe and serious symptoms, such as hæmorrhage, is likely to be excessive

Table I gives the percentage of gastric, duodenal, and anastomotic ulcer with hæmorrhage

Mortality of Hæmorrhage from Ulcer

The true mortality of gastric and duodenal hæmorrhage could be ascertained only by accurate statistics collected by general practitioners Hospital statistics are erroneous, as only the more serious cases are likely to be sent to hospital, and their seriousness is often greatly increased by the excitement and activity involved in their transference from home to hospital , preceding ill health and inadequate early treatment would further tend to increase the mortality Physicians and surgeons are also likely to see only the more serious cases in consultation

GENERAL PRACTICE

Unfortunately general practitioners rarely have sufficient leisure or assistance to keep records from which accurate statistics can be obtained But a death from hæmorrhage is such a dramatic event that it is not likely to be forgotten, so that the number of deaths given by practitioners can be accepted as correct, even if the total number of cases of hæmorrhage seen can be only roughly estimated by those who have been more than a few years in practice We find on inquiry that the incidence of new cases of hæmorrhage in most large general practices is between 1 5 and 2 per annum Twenty seven general practitioners, two of whom practise in London, nine in large towns, and the others in small towns and country districts, who have together been in practice for an average of nineteen years, have seen in all about 677 patients with hæmatemesis and melæna from ulcer Of these only 9 have died , these include the only 3 among the 677 who underwent operation This gives a mortality of 1 31 per cent If we make the more than ample allowance of 100 per cent for possible exaggeration in the number of cases seen we still have a mortality of only 2 6 per cent

HOSPITAL STATISTICS

The following statistics were obtained by Dr A M Bubey from an analysis of all cases of ulcer admitted under the care of A F H from the time he took charge of beds in Addison and Mary wards at Guy s Hospital late in 1919 to the end of 1935 All of the cases included as " hæmorrhage on admission" had had bleeding sufficiently severe to necessitate admission to hospital and all of them bled very shortly before entry to the wards, only 3 having bled as long as forty eight hours before

During the years 1919–35 inclusive there were 371 cases of chronic gastric duodenal, and anastomotic ulcer admitted Of these 82, or 22 per cent , had bled within forty eight hours of admission in 32 of the 82 or 39 per cent there was a history of an earlier hæmorrhage which in many cases was several years before, in one case twenty years before, admission In 106 of the total 371, or 29 per cent , a previous hæmorrhage was recalled This figure is too low for of the 371 case records 50 were incomplete Of the 82 cases admitted for hæmorrhage 54 had gastric ulcers (66 per cent) 22 duodenal ulcers (26 per cent), and 6 anastomotic ulcer (8 per cent) As there were 191 gastric ulcers 167 duodenal ulcers and 10 gastro jejunal ulcers in the series (in addition to 3 with both gastric and duodenal ulcers), the proportion of cases admitted for hæmorrhage in gastric ulcer was 27 per cent , in duodenal ulcer 13 per cent , and in anastomotic ulcer 60 per cent

In 4 cases death was directly attributable to hæmorrhage The mortality rate for the whole group of cases admitted for hæmorrhage is therefore 4 in 82, or 4 8 per cent In the first of the fatal cases glands suggestive of carcinoma were found post mortem, but unfortunately the microscopical report is lost If the ulcer was malignant, the mortality from hæmorrhage from simple ulcer would be reduced to 3 in 82, or 3 6 per cent The mortality rate from hæmorrhage of patients admitted for hæmorrhage (82) or with a history of one or more hæmorrhages is 4 out of 156, or 2 5 per cent , for reasons given above this percentage is certainly too high The mortality from hæmorrhage of all cases of ulcer, including those which have never bled, is 4 out of 371, or 1 1 per cent

From the histories of the patients who died and their autopsy findings it would appear that Cases 1 and 4 might possibly have been saved by surgery

CASE 1 —Female, 53, admitted for three successive hæmorrhages just before entry She gave a history of hæmorrhage one year ago The day after admission there was a small hæmatemesis Three weeks later four hæmorrhages occurred and she died the next day " A huge gastric ulcer was found, with a large gaping artery at its base Glands were present suggestive of carcinoma "

CASE 2 —Male, 48, gave a history of a severe hæmorrhage eighteen months before Two days after coming into hospital he had a severe hæmorrhage The following day he had another severe hæmatemesis and died soon afterwards " On the lesser curvature slightly nearer the pylorus than the cardia was a large saddle backed ulcer with smooth base and raised sharply defined edges The ends of two small arteries lightly plugged with clot were visible in its base *It was firmly adherent to the pancreas* at about its middle, which was converted into a fibrous sac containing the somewhat dilated and reddened pancreatic duct The pancreas was indurated "

CASE 3 —Male, 29 admitted for hæmatemesis Nov 18th 1930 He had other severe hæmorrhages in the ward for which repeated transfusions were given, but he died Dec 22nd " A perforation which would admit the tip of the little finger was seen on the anterior surface of the first part of the duodenum It was shut off from the abdominal cavity by the transverse colon which acted as a roof A considerable amount of blood tracked from the perforation backwards into the lesser sac, which contained one or two ounces of blood clot Almost the entire circumference of the duodenum was occupied by a chronic ulcer, measuring 1 in by ½ in., surrounded by overhanging and thickened fibrous edges On the floor of the ulcer a vessel had been completely divided so that the mouth of the proximal and distal ends were both gaping On cutting through the floor of the ulcer at least 4 mm of white scar tissue was encountered and was found to be adherent to the pancreas "

CASE 4 —Male, 43, admitted for severe hæmatemesis nine hours previously Two large hæmorrhages occurred in the ward. Three transfusions were given, but the patient died nine days after entry A large eroded vessel was found at the base of an acute gastric ulcer on the lesser curvature

ANALYSIS OF CASES SEEN IN CONSULTING MEDICAL PRACTICE (J A R)

The cases which I see in consulting practice include patients from various classes, excepting only the poorest class In a considerable proportion of my private cases I have been called in during an active hæmorrhage Others have been referred to me soon after their recovery from such a hæmorrhage Others again have been seen for dyspeptic symptoms, but a clear account of one or more hæmorrhages has been obtained and entered in my notes Very few have suffered the disadvantage of transportation while bleeding The great majority were promptly diagnosed and treated. Only a very small minority were given transfusions of blood All had definite melæna or red hæmatemesis at intervals of months or years Many patients had recurrent hæmorrhages

In my analysis (Tables II and III) I have divided the hæmorrhages into severe and slight. Some of the slight cases could probably with reason, have been transferred to the severe group The cases which were classified as severe' were definitely described as such or were in bed for a period of weeks or were recorded as having hæmoglobin figures of 50 per cent or lower The duodenal and gastric ulcers and the anastomotic including other post-operative ulcers were at first separately considered but only the collective figures are here given One untraced case of bleeding peptic ulcor is included for the purpose of this analysis among the fatalities

TABLE II

Incidence of Hæmorrhage in Duodenal Gastric and Post operative Ulcers (J A R.'s series)

(a) Total cases D U 563 G U 131 post-op U 60	754
(b) Total cases with hæmorrhage (severe and slight)	258
(c) Total cases with severe hæmorrhage	128
(d) Total hæmorrhages in 258 cases with hæmorrhage	390
(e) Total severe hæmorrhages in 128 cases with severe hæmorrhage	153
(f) Total deaths from hæmorrhage (complicated and uncomplicated)	10
(g) Total deaths from hæmorrhage uncomplicated by old age or by other illness which would have prohibited surgery	4

TABLE III

Mortality from Uncomplicated Hæmorrhage (J A R's series)

	Per cent
(a) Mortality from uncomplicated hæmorrhage in ulcer (754 cases)	0 5
(b) Mortality from uncomplicated hæmorrhage in cases of ulcer with hæmorrhage (258 cases)	1·6
(c) Mortality from uncomplicated hæmorrhage in cases of ulcer with severe hæmorrhage (128 cases)	3 1
(d) Mortality from uncomplicated hæmorrhage in all hæmorrhages (390 cases)	1·0
(e) Mortality from uncomplicated hæmorrhage in all severe hæmorrhages (153 cases)	2·6

There were no deaths from hæmorrhage among women with duodenal ulcer Duodenal ulcer was five times as common in men as in women in this series. Of the fatal hæmorrhages from gastric ulcer 2 were in men 2 in women

There were no deaths from hæmorrhage among the cases of anastomotic ulcer

The ages in the fatal cases of uncomplicated hæmorrhage were 55 50 36 and 26

The ages in the six fatal cases complicated by old age or other illness were 80 72 67 60 56 52 The complicating illnesses in the last four of these were gastric uræmia heart failure cellulitis of the arm and aortic disease respectively

Analysing the four fatalities from uncomplicated hæmorrhage we find that the youngest, aged 26, a case of duodenal ulcer confirmed radiologically was referred to me with an eighteen months history of severe epigastric pain with radiation through to the back suggesting a posterior ulcer involving the pancreas He went home for treatment and a few days later succumbed to an enormous hæmorrhage. A gastric surgeon of wide experience declined to operate

The second patient aged 36 had a history of ulcer dyspepsia going back at least six years. I was called to see him in an exsanguinated and emaciated condition ten days after a severe hæmatemesis. Melæna had continued. The pulse rate was 120 He died immediately after a blood transfusion.

The third patient was aged 55 He had had symptoms of a gastric ulcer for several years He was seen and admitted to hospital after a severe hæmorrhage and died in spite of routine treatment and a blood transfusion.

The fourth case aged 50 was not traced, her doctor having left the country For purposes of the analysis this case has been counted as a fatality

The suggestion that subsequent bleedings are more serious than a first bleeding is not supported by this series The 4 fatal uncomplicated hæmorrhages were all first hæmorrhages This agrees with Crohn s statistics concerning 101 cases of severe hæmorrhage from ulcer at Mount Sinai Hospital there was no previous hæmorrhage in any one of the 9 fatal cases 4 under medical treatment and 5 after operation

The number of subsequent hæmorrhages in individual non fatal cases varied from 1 to 9 The numerical excess of total hæmorrhages over the cases with hæmorrhage was 132 The excess of total severe hæmorrhages over the cases with severe hæmorrhage was 25

Surgery for Hæmorrhage from Ulcer (A F H)

There have been 586 cases of ulcer (110 gastric 379 duodenal, and 97 anastomotic) in New Lodge Clinic between February 1921 and February 1936 and in 3 of these all duodenal, the patient has died from hæmorrhage They were the only cases recognised as being unlikely to recover with medical treatment and they were therefore the only ones which were operated upon whilst still bleeding But surgery failed to save them not because their condition was too serious at the time of the operation for in each case transfusion had raised their hæmoglobin to a safe level, but because the three surgeons concerned, all very experienced very competent and very courageous had to content themselves with indirect operations, as they could not excise the ulcer on account of the adhesions and friable character of the inflamed tissues

In the first patient, a man of 55 a very large ulcer was found on the upper and posterior wall of the duodenum, half an inch from the pylorus invading the pancreas The gastroduodenal and right gastro-epiploic arteries were tied, the ulcer was invaginated with catgut sutures, and a gastrojejunostomy was performed. The hæmorrhage however continued and in spite of two further transfusions he died the following day

The second case that of a man of 39 was an example of familial duodenal ulcer one brother having died from perforation of a jejunal ulcer and another from duodenal hæmorrhage The patient himself had had three operations for ulcer before the final one which preceded his death A gastrojejunostomy was performed in 1916 for a duodenal ulcer which had been present for a year ; in 1925 a callous gastrojejunal ulcer was excised and a new gastrojejunostomy performed subsequently a jejunal ulcer which had almost perforated into the transverse colon was excised and the normal anatomy restored. In 19 8 a new duodenal ulcer developed, which soon led to pyloric obstruction and serious hæmorrhage The patient died in spite of partial gastrectomy with duodenal exclusion and infolding of the ulcer The surgeon wrote to me :

I am very glad that I did not go on any further and deal with the mass in the neighbourhood of the first part of his duodenum I should certainly have slain him on the table "

The third patient a man of 37 had had symptoms of duodenal ulcer since he was a boy He had five very severe hæmatemeses in the last five years, the third a month before admission. He was admitted on Sept 3rd 1935 From that time he had almost daily hæmorrhages his hæmoglobin dropping from 92 per cent on Sept 4th to 3[illegible] per cent on the 16th As the hæmorrhage continued in spite of treatment an operation was performed on Oct 6th after three transfusion which raised his hæmoglobin to 68 per cent His urine was normal and his systolic blood pressure 150 mm, but his blood-urea varied between 54 and 86 mg per 100 c cm, although he was given no alkalis After the separation of a large mass of dense adhesions the duodenum was found to be much scarred and acutely inflamed over its whole circumference It was obvious that excision was impossible and that the bleeding point could not be dealt with directly, as the incision would have had to cross the ulcer A partial gastrectomy with duodenal exclusion was therefore performed He continued to bleed, and in spite of further transfusions his hæmoglobin fell to 28 per cent and his blood urea rose to 432 mg per 100 c cm on the day of his death (Oct 11th)

Post mortem an enormous single ulcer was found occupying the entire circumference of the duodenum except for about 1 cm on the lesser curvature The gastro-duodenal artery with a hole in its centre was exposed in the centre of the ulcer The base of the ulcer was adherent to both the inferior vena cava and the common bile duct so that neither excision nor ligature of the exposed artery would have been possible It was clear too that neither medical treatment nor any indirect operation could have saved him

Of the many cases of severe hæmorrhage from ulcer seen by A F H among private patients before the war in 1919 and 1920, and outside New Lodge Clinic since 1920 only one died from hæmorrhage—a patient whose fatal hæmorrhage in 1914 followed immediately after a gastrojejunostomy for a duodenal ulcer which had never bled before An operation was advised on account of hæmorrhage in only one of these cases seen in 1913

The patient a man of 60 with severe arterio sclerosis, was urged to have a gastrojejunostomy performed when he was seen for the first time some months before his hæmorrhage, as he had a very long history of duodenal ulcer which had led to severe pyloric obstruction He refused to submit to surgery, and continued to wash his stomach out two or three times a day as he had done for many years Three months later he had a severe hæmorrhage which was repeated at the end of a week's starvation, when he was seen for the second time An immediate operation was advised The next morning Lord Moynihan found an enormous duodenal ulcer producing pyloric obstruction he performed a gastrojejunostomy and cut off the blood supply to the ulcer by overlapping sutures round it The patient did very well he died four years later from pneumonia without having had any recurrence of gastric symptoms

The alarm engendered by the appearance and circumstances of a grave internal hæmorrhage, improved surgical preparation and technique, and subservience to the idea that an attempt should be made to control bleeding mechanically at its seat of origin have between them been allowed to constitute a plea for bolder and more drastic action We hope that we have shown that while such action may indeed be dramatic and is certainly courageous, and while it may frequently achieve success in skilful hands it can only in very exceptional circumstances be regarded as judicious In less experienced hands we fear that it will immediately increase the mortality from this accident

General Treatment

Of conservative treatment which is not always accorded the detailed attention which it deserves, the following summary should suffice When local conditions are favourable it should be carried out without transportation of the patient When transportation is essential the optimum moment should be chosen for it and the completest possible comfort and immobilisation should be secured for the patient who must be kept warm and recumbent In all cases a quarter of a grain of morphia should be given at once hypodermically and repeated at intervals, judiciously and in accordance with the needs of the case, during the first 24–48 hours This and watchful nursing are the most important prescriptions All mouth feeding should be forbidden for 24 or 48 and in rare cases 72 hours Longer starvation in severe cases is unwise In slight cases it is unnecessary A closer study of the advantages of earlier and more liberal mouth-feeding in severe hæmorrhage is needed The mouth may be rinsed, but at first not even water should be swallowed Normal saline solution, from half to three quarters of a pint, slowly administered by rectum, should be given four hourly By raising the foot of the bed on a block the pressure in the rectum is reduced and the fluid is more easily retained

It is rarely necessary to give any treatment for the constipation which occurs as a result of the starvation and administration of morphia, as the bowels generally open on the third day after one of the injections of saline solution

Injections of proprietary hæmoplastic sera are of no value, and the claim that they encourage coagulation has not been substantiated (Christie and Gulland)

The hygiene of the mouth must be attended to, for the risk of parotitis in the more serious cases is considerable

When the anxious earlier phase has passed, medical treatment as for an uncomplicated ulcer is gradually instituted Investigation with X rays and test meal should be postponed until the patient's general condition and hæmoglobin percentage justify movement This means waiting for three or four weeks, by which time it is often found, especially with gastric ulcers, that no abnormality can be discovered with the X rays This appears to be due to acceleration in the healing of an ulcer after a hæmorrhage, a belief which receives confirmation from the rapid disappearance of occult blood from the stools Chemical and spectroscopic tests in the majority of cases become negative at an earlier date after the beginning of treatment if a gross hæmorrhage has occurred than in cases in which there has been no obvious hæmatemesis or melæna

Transfusion

We are inclined to think that transfusion is not without danger, a conclusion also reached by Cullinan and Price in their study of cases treated at St Bartholomew's Hospital It is true that transfusion is not likely to be used except for severe cases, but the mortality appears to be higher where transfusion is often employed than elsewhere Christiansen (1934) states that the mortality has doubled in the Kommune hospitalet, Copenhagen, since transfusion has become common practice

Cases should be selected for transfusion with more discrimination than is usual in hospitals where the facilities are greatest, and care should be taken to give not more blood than is required As Cullinan and Price have pointed out, there is no evidence that transfusion helps to arrest hæmorrhage, in fact it occasionally has the opposite effect being followed almost at once by a return of bleeding in cases in which hæmorrhage has ceased Moreover the reaction following transfusion is sometimes severe, and this may be the direct cause of death without further hæmorrhage in patients who are already in a very weak condition

Transfusion should in general not be given unless the hæmoglobin percentage is under 30 and the patient appears to be in danger of death from anæmia About ten ounces is sufficient, and transfusion should not be repeated unless the hæmorrhage recurs Transfusion is not required for the restoration of the blood to the normal level as the rise to normal is sufficiently rapid when thirty grains of iron and ammonium citrate are given three times a day

A man of 25 whose hæmoglobin had dropped to 15 per cent after repeated severe hæmorrhages from a duodenal ulcer received a transfusion of 9 oz. of blood at once Iron and ammonium citrate 30 grains three times a day was then administered The hæmoglobin rose from 15 to 30 per cent on the third day 40 per cent on the fourth 60 per cent on the seventh 68 per cent on the fifteenth and 85 per cent on his discharge on the fortieth day after admission

Clotting is most likely to occur when the circulation is at a low ebb with the blood pressure low and the patient collapsed. A rapid rise in blood pressure may lead to recurrence of hæmorrhage which would not take place if the rise in hæmoglobin is as gradual as it is with the administration of iron

If it is decided that an operation must be performed in order to save the patient's life transfusion should be given with the object of raising the hæmoglobin to a level which will make the operation safe It is worth noting however that the only successful operation for hæmorrhage on a case of our own was performed before the war and consequently no preliminary transfusion was given although the patient, a man of 60 was in a condition of extreme anæmia and had been completely starved for eight days Whether continuous drip transfusion by means of which the hæmoglobin percentage can be raised rapidly from 20 or 30 per cent to 80 or 90 per cent. has strong advantages over a single transfusion of twenty ounces given before operation and a second transfusion of twenty ounces given during or immediately after the operation is a matter deserving of further inquiry We have never seen a case in which operation failed to save the patient because the hæmoglobin was insufficiently high; the technical difficulties caused by the size, position and adhesions of the ulcer have always been the cause of failure Continuous transfusion is likely to be actually dangerous if the surgeon is unable to secure the bleeding point, as the sudden rise of blood pressure would be likely to cause a recurrence of hæmorrhage after an indirect operation such as gastrojejunostomy or partial gastrectomy with duodenal exclusion performed for a bleeding duodenal ulcer

There are other factors which contribute to death following hæmorrhage besides hæmoglobin deficiency Among these loss of salt and fluid and a rising blood urea should be especially worthy of study

Iron

After a single small hæmorrhage regeneration of blood is rapid and no special treatment is required On the other hand after repeated small hæmorrhages or after a single massive hæmorrhage recovery can be greatly hastened by the administration of iron in adequate doses by mouth Iron and ammonium citrate is always well tolerated and the rapid rise of hæmoglobin following its use appears to hasten the healing of the ulcer Unless an operation is contemplated it is thus unnecessary to give more than a single transfusion as when thirty grains of iron and ammonium citrate are given three times a day there is generally an average gain of between 1 and 2 per cent of hæmoglobin every day until the normal level is reached. Table IV gives the hæmoglobin percentage in a series of cases in which weekly estimates were made whilst iron was being given for the anæmia resulting from hæmorrhage after an ulcer The patients were not transfused and were on the ordinary strict ulcer diet

TABLE IV

Week of treatment	M 35 D U	F 63 G U	F 40 G J U	M 4[illegible] D U	M 60 D U
—	50	45	62	58	62
1	69	57	87	78	64
2	80	60	90	95	70
3	90	75	—	—	70
4	—	93	—	—	—

Conclusions

1 The *incidence* of hæmorrhage is about 30 per cent. in gastric and duodenal ulcer and 45 per cent in anastomotic ulcer

2 *Mortality*—The danger of hæmorrhage from ulcer has been grossly exaggerated in a number of papers recently appearing in British journals The mortality among patients with hæmorrhage from an ulcer is about 1 5 per cent. in general practice This figure is the nearest possible approach to the natural mortality As the incidence of hæmorrhage in cases of ulcer is about 30 per cent. the mortality from hæmorrhage in all cases of ulcer whether they have previously bled or not is about 0 4 per cent The mortality of cases of ulcer admitted into Guy's Hospital under A F H on account of hæmorrhage is 4 8 per cent. The mortality from hæmorrhage in patients with a history of hæmorrhage from ulcer or admitted for ulcer is under 2 5 per cent and the mortality from hæmorrhage of all cases of ulcer including those which had never bled is about 1 per cent Comparing these figures with a private series (J A R) we find a mortality of 3 1 per cent from hæmorrhage in cases of severe hæmorrhage and a mortality of 0 5 per cent from hæmorrhage in all cases of ulcer

3 *Surgery as prophylaxis*—As the total mortality of all operations performed for gastric and duodenal ulcer is considerably greater than that of the mortality from hæmorrhage among all cases of ulcer and as hæmorrhage is by no means rare after operations on patients with ulcer who have already bled it is obvious as Gordon Taylor has also pointed out that surgery cannot be regarded as a means of prophylaxis against fatal hæmorrhage. According to Balfour hæmorrhage occurred after operation at the Mayo Clinic in 13 per cent of cases of ulcer with a previous hæmorrhage, but in only 0 9 per cent. of cases with no history of previous hæmorrhage Even partial gastrectomy does not prevent a reoccurrence of hæmorrhage We have seen four cases in which hæmorrhage recurred within a year of the performance of a subtotal gastrectomy for ulcer

4 *Surgery as treatment*—It is generally not very difficult to recognise the rare cases of bleeding ulcer which will not recover from medical treatment Unfortunately they are the same cases as those in which direct treatment of the bleeding point by operation is likely to be impossible so that even when the operation is performed by surgeons of great experience and the patient has been adequately prepared by transfusion the mortality after operation must be extremely high Among the 4 fatal hospital cases under A F H 2 might possibly have been saved by operation on the other hand an operation failed to save any of the 3 fatal New Lodge Clinic cases and the 6 fatal cases among the [illegible] collected from general practice included the only 2 which underwent operation

There can be little doubt that operation for a large proportion of cases after continuous transfusion, as recently advised by Gordon Taylor, would lead to a considerable increase in the death rate, as the mortality of interval operations for ulcer is at least as high as the actual mortality from hæmorrhage

5 *Early feeding*—There is no evidence to show that malnutrition was a factor in any of the fatal cases among the series analysed in this paper It

Lenhartz and recently by Holmgren and Meulengracht, would have prevented any of the deaths in the series of cases which form the basis of this investigation

6 *Transfusion and iron*—The remarkably low mortality among cases seen in general practice indicates that the old fashioned treatment with rest in bed, starvation, and morphia is all that is needed in the vast majority of cases, as very few received transfusion or underwent operation In spite of this we believe that transfusion may occasionally save the life of patients who would otherwise die from anæmia, and that it is an almost essential preliminary in the rare cases in which operation is indicated Apart from its use as a preliminary to operation a *transfusion should not be given unless the percentage* of hæmoglobin is under 30 per cent, not more than ten ounces of blood should be introduced at a time, and the transfusion should not be repeated unless hæmorrhage recurs There have been favourable reports on the immediate benefits of continuous drip transfusion (Gordon Taylor), but it is doubtful whether the method should ever be employed in cases of gastric hæmorrhage excepting as a preparation for immediate surgery

Large doses of iron and ammonium citrate can be safely given from the third day following a hæmorrhage, they lead to a rapid return of hæmoglobin to a normal level and in this way greatly hasten convalescence

7 If operation is reserved for the very rare cases in which it seems probable that the source of bleeding is a large hole in a sclerotic vessel exposed at the base of a chronic ulcer, and if transfusion is given only under the circumstances and by the method described above, it should be possible to obtain a still further reduction in the already low death rate from hæmorrhage in gastric, duodenal, and anastomotic ulcer

Fellowship of Medicine and Post Graduate Medical Association—An afternoon course in dermatology, which is open to non members, will be given at St John's Hospital (Jan 4th to 31st), an all-day course in cardiology, also open to non members, at the National Heart Hospital (Jan 11th to 22nd) Other courses will be given on advanced urology at St Peter's Hospital (Jan 18th to 30th) and on chest diseases at the Brompton Hospital (Jan 25th to 30th) A course of surgical tutorial classes, specially intended for candidates for the F R C S (final) examination, will be given at the National Temperance Hospital on Tuesdays and Thursdays at 8 30 P M from Jan 12th to March 4th Further particulars may be had from the secretary of the fellowship 1, Wimpole-street London W 1

BLOOD CHANGES AFTER SURGICAL OPERATIONS

By W W Walther, M B Lond

DIRECTOR OF PATHOLOGY AND LYLE RESEARCH SCHOLAR,
QUEEN MARY'S HOSPITAL FOR THE EAST END,
STRATFORD, E *

The methods used were as follows —

1 Hæmoglobin estimations by the Haldane colorimetric method, on all cases

2 Estimations of the relative cell and plasma volume by hæmatocrit, confirming the hæmoglobin estimations

3 Plasma chloride estimations on many of the cases by the method of Claudius (1924)

4 Plasma protein estimations on the majority of the cases, *using a modification of the method of Wong* (Peters and Van Slyke 1932)

Blood was obtained from a deep ear puncture and run into a small tube containing a minimal quantity of heparin. 0 4 c cm was collected without squeezing Except in certain cases where venous blood was obtained simultaneously, only those samples of capillary blood which flowed freely and spontaneously were used for analysis In a number of cases venous blood was also used. The patients were bled before operation and at frequent intervals (usually daily) afterwards

The patients are grouped under the following heads according to the after-treatment they received —

Group 1 (12 cases)—No special treatment

Group 2 (27 cases)—Treated with rectal infusions or "forced fluids" by mouth.

Group 3 (9 cases)—Treated with intravenous saline

Unclassified (2 cases)

The results of hæmoglobin, chloride, and protein estimations are presented separately for each group

Results

Hæmoglobin—It is obvious that hæmorrhage during operation reduces the amount of hæmoglobin and the number of red cells in the body, but the change does not become evident in blood samples until *dilution has begun to restore the total volume* to normal Group 1 patients who received no excess of fluids after operation, or were even restricted in their fluid intake, showed a slow reduction of hæmoglobin percentage, which did not reach its new level, determined by the amount of hæmorrhage, for several days This means that the normal process of dilution took a long time Under these conditions recovery was slow and many of the patients complained of severe thirst and showed the dry tongue and sunken features found in dehydration Figs 1 and 2 are examples of results obtained in this group Group 2 consists of patients who were more ill and who were therefore given rectal infusions or forced fluids by mouth Their blood dilution (and therefore restoration of the blood volume) was more rapid, and so was their recovery Figs 3 and 4 are representative

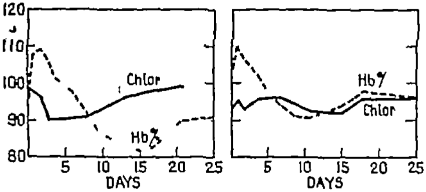
The accompanying Table summarises the statistical information, relevant to the present investigation, which can be derived from the data

The values of *t* given at the end of the Table were obtained by comparing the two groups by the Fisher *t* test technique These values do not reveal significant differences between the groups either for initial or for

---

* This research has been made possible through the generosity of Sir Leonard Lyle Bt deputy president of the hospital.

FIG 1 FIG 2



FIGS 1 & 2.—Chlorides (millimols) and hæmoglobin (per cent) of untreated patients who received no excess of fluids after operation.

Days refers to time after operation when specimen was obtained Results recorded at 0 days refer to specimens obtained before operation

final hæmoglobin values but the difference in the time taken to attain *maximum dilution is highly significant* This result implies that if the extent of the dilution of the hæmoglobin of the blood as measured here is a satisfactory indication of the restoration of plasma volume after operative hæmorrhage then the restoration occurs in the treated cases more quickly than in the untreated cases and the difference is highly significant

The control group (the untreated cases Group 1) is small in size and, since both are heterogeneous with respect to the sort of operation performed, it may not be strictly comparable with the experimental group (the treated cases, Group 2)

Chlorides—No important reduction in the plasma chlorides was found but some cases treated with large quantities of saline per rectum developed hyperchloræmia with hydræmia Fig 3 is an example of this

Proteins—The results were compared on the following basis If blood is diluted the hæmoglobin and protein will show the same percentage fall provided that the protein is expressed (like the hæmoglobin) as a fraction of whole blood Of the 37 patients thus investigated 21 suffered no loss of protein after the operation beyond the loss due to hæmorrhage The other 16 showed a loss which was rapidly restored in 11 of them

Sign obtained thus Untreated cases—treated cases
Two cases from Group 1 not included owing to complications

Of 12 untreated cases (Group 1) 6 suffered a loss of protein and 6 did not Of the 19 cases receiving additional fluid (Group 2) only 5 showed a temporary loss of protein while 14 lost none in fact they showed a steady increase Of 6 cases receiving intravenous salines (Group 3) 5 lost protein which was *not recovered in three of them and only* 1 did not (case described later see Fig 5)

A temporary rise of hæmoglobin percentage above the pre-operative figure occurred in 14 of the 16 cases sustaining a loss of protein but in only 3 of the 21 who gained protein

Pulmonary œdema—Four cases developed pulmonary *œdema while the plasma protein was below* the normal of 5 8 per cent (Figs 5 and 6) Two of these sustained a temporary loss of protein one a permanent loss and one described later a steady increase In this case and in the two whose protein loss was only temporary the abnormally low plasma protein percentage was due to rapid dilution of the blood Only two other cases showed a temporary diminution of their plasma protein and these had no symptoms of pulmonary œdema In three of the four cases of pulmonary œdema the condition developed after the administration of intravenous saline.

FIG 3

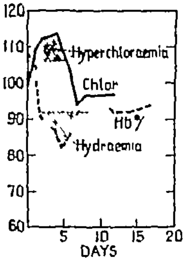

FIG 3.—Chlorides and hæmoglobin of a patient who received 8½ pints of saline by rectal infusions within 3 days

FIG 4

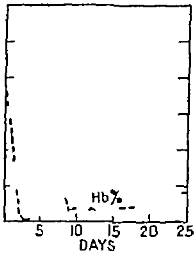

FIG. 4.—Hæmoglobin of a patient who received 5 pints of saline and 5 pints of glucose solution per rectum within 4 days

Discussion

A number of workers[1 2 5 8] have shown that shock is accompanied by increased concentration of the blood-cells particularly in the capillaries Cannon Frazer and Hooper (1917) and Bazett (1918) found a temporary concentration of red cells in the blood after operations Bazett (1918) and Robertson (1935) have shown that variations in the hæmoglobin percentage

FIG 5

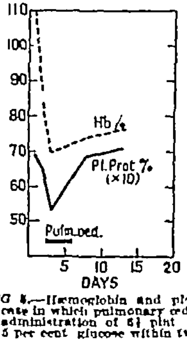

FIG 5.—Hæmoglobin and plasma protein percentages in a case in which pulmonary œdema developed after intravenous administration of 6½ pint of alternate normal saline and 5 per cent glucose within two days

FIG 6

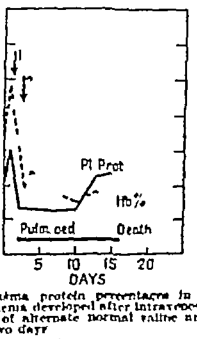

FIG. 6.—Hæmoglobin and plasma protein percentages in a case of postoperative pulmonary œdema At I the patient received 6 oz of blood and 10 oz of gum saline intravenously At II he received 3 pints of normal saline and 1 pint of 5 per cent glucose intravenously

are a measure of variation of the total circulating blood volume

It is clear that the untreated patients of Group 1 suffered a fairly prolonged diminution of blood volume, while the treated Group 2 recovered the blood volume much more rapidly in spite of the fact that the patients of this group were more ill in the first instance A considerable proportion of the patients in Group 1 and in the more seriously ill Group 3 lost protein in excess of what could have been lost by hæmorrhage as shown by the hæmoglobin percentage variation This must have been due to loss of plasma which has been shown to occur in shock[2,3,8] Another phenomenon of shock—namely, increased concentration of the red cells and hæmoglobin above the preoperative level (see Fig 1)—was present in nearly all the patients who lost protein These cases can reasonably be said to have suffered from shock Adequate treatment with fluids mostly prevented the changes typical of shock

TREATMENT

As preventives of shock, there seems little to choose between fluids per os and fluids per rectum, but excess of salt is objectionable owing to the possibility of causing hydræmia (see Fig 3)

The intravenous route is often disappointing *Samson Wright (1936) states that though oral or rectal* saline may increase the blood volume intravenous saline is not retained in the vessels and is soon lost through the kidneys Further, Maizels and Smith (1934) have shown that since physiological saline is nearly twice as strong in chlorides as blood plasma a strain is thrown on the kidneys to excrete the chlorides while retaining the water, and in this the kidneys may fail with the result that the patient becomes more dehydrated than before On the whole in the present series, alternate physiological saline and 5 per cent glucose in water by the continuous drip method was more successful intravenously than physiological saline alone

The chief objection to intravenous fluid is the risk of pulmonary œdema Dilution of the plasma proteins and therefore reduction of the effective osmotic pressure, occurs first in the pulmonary circulation and if the plasma protein percentage is low to begin with the osmotic pressure may be reduced to such an extent as to allow leakage of fluid from the vessels into the lung Of the 4 cases of pulmonary œdema all had a low protein percentage and in 3 the complication followed intravenous injection of saline

A clue to the greater efficiency of rectal saline compared with intravenous saline is found in the increase of total circulating protein which took place during the administration of rectal saline Fluid absorbed from the rectum must traverse the liver before reaching the general circulation and it seems reasonable to suppose that a certain amount of protein is 'picked up' from the liver thus raising the osmotic pressure of that particular sample of blood to an extent great enough to prevent loss of fluid from it via the capillary endothelium Intravenous fluid has to traverse the systemic capillaries before it can reach the liver and the dilution of the protein may be sufficiently great to allow transudation of the fluid before it can get a chance to reach the liver Hence the greater danger of pulmonary œdema after intravenous saline than after rectal saline

When the need to restore the blood volume is urgent a more rational intravenous fluid is one containing the material protein which is necessary to maintain the osmotic pressure of the blood Such a material is plasma Since urgent cases usually show the increased concentration of the red cells typical of shock and since there is an increasing danger from raised blood viscosity causing stasis, acidæmia, and poisoning of the capillary endothelium, which will in turn bring about further fluid loss and blood concentration, it must surely be exceedingly unwise to give a transfusion of whole blood. Starling (1909) states that if blood is transfused into an animal which has not lost blood, the fluid and a proportion of the protein leave the circulation causing a concentration of red cells Although this will not necessarily occur in a patient with an already depleted blood volume, there cannot fail to be an increase in the number of circulating red cells, and it seems a pity to superimpose a polycythæmia on shock *One can only conclude that the ideal* treatment of an urgent case is plasma transfusion

CASE REPORTS

Three cases are worthy of special description

BURNS LOSS OF PROTEIN

A woman of 27 was admitted with second and third degree burns over back, buttocks, and both legs, rather more than half her body surface being involved. After treatment with tannic acid she was found to have a blood pressure (systolic) of 108 the pulse rate being 124 Capillary and venous hæmoglobins were 114 and 116 per cent respectively and the plasma protein was 6 75 per cent in both Twenty four hours later she was almost pulseless, the blood pressure was 100, and the capillary and venous bloods gave hæmoglobins of 160 and 130 per cent respectively Three pints of a gum saline solution were given slowly into a vein with considerable improvement in the pulse, though the rate remained at 140 An ear puncture flowed freely giving a hæmoglobin of 100 per cent and a plasma protein percentage of only 3 44 Twelve hours later the pulse was weaker, but the capillary hæmoglobin remained at 100 per cent She died four hours later

The findings here are in agreement with the work of Blalock (1931) who showed that whole plasma was lost from the circulation in experimental burns, and of Underhill and his associates (1923) who demonstrated blood concentration in a series of accidental burns Incidentally the hæmoglobin concentrations obtained by these workers are remarkable When it is considered that with a hæmoglobin concentration of 110 per cent the cells occupy about half of the total blood volume, their figures of 200 per cent or over must indicate that the blood consisted only of cells No doubt the blood was obtained from capillaries as a result of considerable squeezing

Inasmuch as these cases of severe burns show great blood concentration from plasma loss, the rational treatment is to use plasma transfusion to replace what is lost Blood transfusion, which supplies more cells to an already concentrated blood, cannot be recommended

INTRAVENOUS INFUSION, PULMONARY ŒDEMA, ? HISTAMINE SHOCK

A boy, aged 8 years was operated on early one morning as an emergency some 5 ft of small intestine which had been strangulated by a fibrous band and had become "gangrenous" being freed and returned to the abdomen under local anæsthesia. He was seen a few hours later when his pulse was of small volume and 140 per minute In contrast to the usual appearance of shock with its greyish pallor he was bright red in the face, with the flushed appearance one might expect from the presence in the circulation of histamine or some vasodilator substance (Knight and Slome 1936)

The effect of treatment on the blood concentration is shown in Fig 5 Except on the first day when venous blood only was used for analysis capillary and venous blood gave the same results Signs of pulmonary œdema were noted two days after the operation and on this day as a result of dilution with intravenous saline the plasma protein was only 5 3 per cent Thereafter recovery was rapid.

This case is of interest because of the very considerable blood concentration which was present without any sign of stasis also because of the good effect of intravenous saline and glucose and the development of pulmonary œdema when the plasma protein had reached a subnormal value

SHOCK WITH RAISED BLOOD ADRENALINE

A laparotomy was done on a man of 73 and, an inoperable carcinoma of the stomach being found, the abdomen was closed. Next day his pulse-rate was 100 with fair volume his tongue was dry his colour normal but the veins of his arms were slightly contracted and would not dilate when a tourniquet was lightly applied above them His capillary and venous hæmoglobin had risen from 79 per cent before operation to 85 per cent while the plasma protein had fallen from 6 13 to 6 per cent Two days after the operation his appearance was remarkably changed. His tongue was dry he was very thirsty in spite of copious drinks his lips were cyanosed and he was slightly breathless The pulse rate was 132 and of poor volume and the blood pressure was 125/85 His face was cold and had a greyish pallor and the capillaries would not empty readily under pressure nor refill when the pressure was released, the blood flowing in them like tar The veins were noted to be much contracted.

Since Freeman (1933) has produced all the phenomena of shock in cats by injection of adrenaline in physiological amounts into their circulation it was decided to perform a blood adrenaline estimation on this patient while he was in his vasoconstricted condition. Using Whitehorn s method (1935) 0·24 ± 0·02 mg of adrenaline was found per litre of blood—a quantity stated to be much in excess of normal. The capillary and venous hæmoglobins were 106 and 90 per cent. and the plasma protein 7 38 per cent An attempt to give intravenous saline failed because the fluid would not pass along the contracted vein. Four days after operation he was slightly better his colour was improved, the pulse-rate was 112 with better volume and the capillaries were not so contracted Capillary and venous hæmoglobins were 96 and 84 per cent and the protein 6 56 per cent

On the following day five days after operation his appearance was completely changed His face was bright red, his pulse was 100 and of good volume the blood pressure was still 125/85 and the capillaries were easily emptied and refilled. The capillary and venous hæmoglobins were each 81 the plasma protein 5 81 per cent and the blood adrenaline nil At 5 A M the following morning the patient died suddenly of a pulmonary embolus.

In this case there was extreme concentration of the blood associated with almost continuous loss of protein from the circulation and greater concentration of the cells in the capillaries than in the veins These changes together with the patient s appearance were typical of traumatic shock The raised blood adrenaline taken in conjunction with the work of Freeman (1933) is significant

Of the factors that may contribute to intravascular thrombosis (Frey 1933) two were definitely present in this case—namely vascular stasis and an increased sedimentation rate already high before operation (20 mm from a column of blood of 100 mm in one hour) and likely to be even higher afterwards (Chauvin Esmenard, and Jaur 1926) And the one condition likely to loosen the clot in an inactive patient was also present later—namely vasodilatation The clot after formation is loosely attached to the vessel wall and this attachment can be severed by the shearing effect of dilatation of the vessel.

Conclusions

1 Patients who have undergone major abdominal operations tend to suffer from anhydræmia, the duration of which depends on the efficiency of the after treatment Improvement in the clinical condition of the patient tends to run parallel with the restoration of the blood volume

2 If left untreated anhydræmia may develop into true shock characterised by concentration of the blood from plasma loss. Even if shock does not appear dehydration may take place and seriously interfere with the patient s comfort and rate of recovery

3 The best method of fluid replacement if the oral route is contra indicated is per rectum preferably by continuous drip The rectal administration of fluids at the rate of over two pints per day shortens the time for blood dilution and for the accompanying improvement in the clinical condition

4 Since no evidence of serious chloride deficiency was found after operation the fluid given per rectum need not contain the chloride excess found in normal saline On the contrary excessive administration of normal saline may even lead to hydræmia

5 Adequate treatment with rectal fluid tends also to prevent the onset of shock as shown by plasma loss and increasing concentration of the red cells in the blood

6 Since pulmonary œdema may result from abnormally low percentage of protein in the plasma and since intravenous fluids tend to lower this percentage the level of the plasma protein should be ascertained before giving fluid intravenously

7 Owing to the danger from protein loss emergency treatment of post-operative shock should preferably consist in intravenous infusion of plasma. Inasmuch as extensive burns lead to much loss of protein the ideal treatment of this condition must be intravenous plasma infusion

8 Blood transfusion for shock and burns is contra indicated in the absence of anæmia or massive hæmorrhage It carries a risk of increasing the already high concentration of the red cells in the blood and so encouraging stasis

I should like to record my thanks to the staff of Queen Mary s Hospital for giving access to their patients, to Dr M Maizels and Dr G R Cameron of University College Hospital for much information and help, to Prof Samson Wright for his valuable criticism, and to Mr W F Floyd of Middlesex Hospital medical school for making the statistical summary of the hæmoglobin results.

FIBRINOLYSIS FOLLOWING OPERATION

By R. G. Macfarlane, M.B. Lond.*

SIR HALLEY STEWART RESEARCH FELLOW, DEPARTMENT OF PATHOLOGY, ST. BARTHOLOMEW'S HOSPITAL, LONDON

A small quantity of blood taken immediately after an operation for cholecystectomy led by chance to the observation of a curious phenomenon. It had been allowed to clot in a centrifuge tube and was left overnight at 37° C. in order that the serum might be obtained when retraction was complete. The next morning, however, it was found that the blood was quite fluid and all trace of the clot, which had been perfectly firm the evening before, had disappeared. A few days later my attention was called, by Dr. L. P. Garrod, to a recent paper by S. S. Yudin, in which the Russian practice of transfusing with blood obtained from corpses was described. In this paper stress was laid upon the fact that persons meeting sudden or violent death were particularly useful donors for a very remarkable reason. If, in these cases, the blood was withdrawn soon after death, it was found that, though coagulation soon took place in the ordinary way, the blood returned to the fluid state in the course of an hour or two, the clots having apparently dissolved. Since it showed no further tendency to coagulate, the addition of anticoagulants was not required, and it could be preserved in this state almost indefinitely, being used for transfusion when needed.

In the light of this paper, therefore, the phenomenon first described began to assume a possible significance, particularly since the fibrinolysis observed by the Russians was associated in their minds with the profound shock experienced before death. The question arose as to whether this fibrinolysis occurred, possibly in a lesser degree, in living persons who had suffered accidental trauma, or undergone surgical operation. Though this problem is at present more of academic interest than of clinical importance it was decided to investigate it. The present paper is a report of the admittedly incomplete and elementary experiments with which this investigation has been begun.

EXPERIMENTS

Patients undergoing surgical operation were selected as being the best subjects to begin with, since blood could be obtained immediately before, and immediately after, the trauma and accurate control therefore obtained. The anæsthetic, of course, introduced a variable factor, but by choosing a series of cases which included the use of inhalation, spinal, and local anæsthesia, it was felt that the effects of these could be determined and eliminated.

At first, attempts were made to repeat the original observation. Blood was obtained by venipuncture before and after operation in about 20 cases, and allowed to clot in centrifuge tubes. These tubes were then incubated at 37° C. and the contents examined in twenty-four hours. In 2 cases complete lysis had occurred at the end of this time in the post-operative blood. In one of these the blood was from a woman who had an operation for cholecystectomy; in the other it was from a woman who had a needle removed from her hand under a local anæsthetic.

In a large proportion of the remaining cases the post-operative clots appeared to be more friable than those obtained from the pre-operative blood, though there was no definite evidence of lysis. The method appeared to be unsatisfactory, since the turbidity of the fluid made it impossible to see the state of the clot without interfering with it. It was therefore decided to experiment with recalcified citrated plasma.

Blood was obtained before and after operation as in the previous series, but was immediately citrated by the addition of one tenth of its volume of 3.8 per cent. sodium citrate solution. It was then centrifuged at slow speed for ten minutes by the clock, and the plasma removed by pipette. Of this, 4 c.cm. was recalcified in each case by the addition of 1 c.cm. of 1.18 per cent. calcium chloride solution, and the tubes containing the clots incubated for twenty-four hours at 37° C. as before. In 2 cases out of 22 examined in this way complete lysis occurred during the period of incubation, one being after nephrectomy, and the other after excision of an epithelioma on the back. Both patients were males and both had general nitrous oxide oxygen and ether anæsthesia.

The remaining 20 cases again showed indefinite signs of lysis; in the majority the post-operative clots were more fragile (in some cases actually fragmented), and the serum more turbid than was the case with the pre-operative controls. The results, however, were inconclusive, and a method of measuring the exact degree of lysis after a definite period of incubation was required. Attempts were made to weigh the clots, after washing and drying, and thus determine the extent of lysis, if any. This project proved to be unsuccessful. It was found impossible to free the close textured plasma clots from adsorbed serum proteins to a satisfactory degree, and inconsistent results were obtained. It was an attempt to overcome this difficulty that led to the production of what appears to be a delicate and satisfactory method of demonstrating fibrinolysis.

In order to reduce the adsorption of serum proteins on to the fibrin that was to be weighed, a method commonly used in the estimation of blood fibrinogen was employed. If 1 c.cm. of citrated plasma be added to 1 c.cm. of 1.18 per cent. calcium chloride solution and 28 c.cm. of 0.85 per cent. saline, subsequent coagulation results in the formation of a fine fibrin reticulum throughout the whole volume of the fluid. This web can be wound on to a glass rod, washed in distilled water, and its mass estimated directly by drying and weighing, or from its nitrogen content by the micro-Kjeldahl apparatus.

It was proposed to prepare two such webs from pre-operative, and two from post-operative, blood, one of each of these to be estimated immediately, and the other two after 24 hours' incubation.

Accordingly blood was obtained from a man about to undergo an operation for the cure of an inguinal hernia, under a local anæsthetic. It was at once citrated, and the plasma obtained as before. The fibrin webs were prepared in the way described in two boiling tubes, one of which was incubated. The other was used immediately to estimate the blood fibrinogen, by the gravimetric method. The whole process was then repeated with blood obtained as the patient was leaving the theatre, the technique being rigidly adhered to.

The pre-operative and post-operative blood fibrinogens were found to be 320 and 310 mg. per 100 c.cm. respectively. The pre-operative and post-operative fibrin webs remaining were left until the next morning

---

* Assisted by an expenses grant from the Medical Research Council.

at 37 C when it was proposed to estimate their mass in the same way The next morning however it was found that this procedure could not be carried out The pre-operative web was intact giving an equivalent of 310 mg per 100 c.cm, but the post-operative web had completely disappeared leaving a clear fluid Similar results were obtained with two cases of partial thyroidectomy the pre-operative clots remaining intact and the post-operative fibrin dissolving in less than 24 hours

The Effect of Operation on Fibrinolysis

G = gas O = oxygen E = ether d = days.

At this stage blood was obtained from 6 normal donors, and fibrin prepared in the same way In these incubation was carried on for longer periods to observe the changes that were likely to occur in normal fibrin under these conditions In one of these there was evidence of some lysis after 48 hours since the web broke up into fragments on gently shaking the tube the other 5 being unaffected by similar treatment These fragments however did not dissolve until two days later By the fifth day one other tube showed the same change but the other 4 were unaffected and when two days later the experiment was discontinued, these were still intact In 4 out of 6 therefore lysis did not occur in seven days in one partial lysis took place in two days and complete lysis in four days and in the remaining one partial lysis had begun by the fifth day but was not complete on the seventh Blood was then obtained from a series of operation cases which are tabulated above In every case blood was obtained within one hour of the operation and usually as the patient was leaving the theatre The pre-operative blood was obtained the day before or before premedication was given in all except 3 cases when it was taken just before the anaesthetic was administered

From the accompanying Table and the 3 cases described previously it will be seen that in 22 cases out of a total of 29 complete lysis of post-operative clots occurred in twenty four hours Of the remaining 7 2 showed increased lysis as compared with the controls and 5 showed none during the period of incubation employed

Experiments were then performed to ascertain if possible the nature of the lysis It appeared to be a physical rather than a chemical change though this has not yet been confirmed The first stage is one of fragmentation of the clot which proceeds until dispersion is complete The fluid remaining is quite clear by ordinary transmitted light but the Tyndall beam is brighter after lysis than before After standing for several days at room temperature the fluid containing lysed fibrin deposits a light precipitate which redisperses on warming or shaking

In 4 cases showing post-operative lysis the following experiment was performed As soon as the fibrin webs had formed they were removed from the fluid washed in two changes of saline and placed in each other's fluid. The results obtained were the same in each experiment and are summarised below —

Tube	Contents.		Lysis in 4 hours
1A	Pre-operative fibrin.	Pre-operative fluid	None
1B	Pre-operative fluid	Post-operative fibrin	Complete
2A	Post-operative fibrin	Post-operative fluid	„
2B	Post-operative fluid	Pre-operative fibrin	None

These results suggest that the lysis therefore is due to some change in the fibrin or some substance adsorbed by it from the serum rather than the presence of a free lysin To differentiate between these alternatives the following experiment was performed Pre-operative and post-operative fibrin washed in saline as before was added to post-operative and pre operative plasma, in a concentration of 1 in 30 in saline, with the addition of a few drops of sodium citrate solution to prevent possible coagulation by any calcium remaining in the fibrin The results were as follows:

Tube	Contents		Lysis in 24 hours
1A	Pre-operative fibrin	Pre-operative plasma	None
1B	Pre-operative plasma	Post-operative fibrin	Complete
2A	Post-operative fibrin	Post-operative plasma	
2B	Post-operative plasma	Pre-operative fibrin	None

These results suggest that the lysis is due to a change integral with the structure of the fibrin itself

In all these experiments of course sterile apparatus and solutions were used and aseptic technique adopted Cultures taken from the contents of tubes after incubation have remained sterile in the cases reported

CONCLUSION

The position therefore is as follows Some change in the fibrin structure occurs as a result of trauma, which under strictly aseptic conditions, results in the dispersion of the fibrin reticulum This change has been observed under the conditions described in 24 out of 29 operation cases, obviously too small a series to be conclusive, but large enough to be suggestive Bacteria do not appear to play a part, since cultures of the fluid containing lysed fibrin are sterile Whether this rapid lysis is merely an acceleration of the normal aseptic lysis, which is regarded by Nolf as the natural sequel to coagulation, remains to be seen Future work will be directed towards the confirmation of its occurrence as described, and to a possible elucidation of its mechanism and significance

My thanks are due to Prof Geoffrey Hadfield and Prof Paterson Ross for their interest and advice, and to those members of the surgical staff of St Bartholomew s Hospital who have given permission for these investigations to be carried out on their cases

CHEST DEFORMITIES IN ASTHMA

By H H Moll, M D Rome, M B Leeds,
M R C P Lond

ASSISTANT PHYSICIAN TO THE GENERAL INFIRMARY AT LEEDS
PHYSICIAN TO THE LEEDS PUBLIC DISPENSARY
AND HOSPITAL

When asthma is of long standing emphysema is nearly always present The distension is the sequel of a functional rather than an organic disorder of the lung and with abatement of the attacks of asthma the lungs gradually empty themselves and return to their original size With recurrent and protracted attacks, however, the approximation to normal is less complete after each attack, and the chest wall becomes distended and fixed In well established cases the shoulders are lifted and the back is hunched The sternum bulges prominently and may form a typical pigeon breast The chest is rounded in its upper half, there is a deep lateral sulcus, and the base is narrow and contracted The appearance of the chest is that of an inverted flask This deformity is quite different from the "barrel chest" usually associated with genuine hypertrophic emphysema In the barrel chest the upper part of the thorax is not unduly expanded the widening of the chest increases progressively from above downwards, and reaches its maximum at the base Dorsal kyphosis and anterior pigeon deformity are not prominent features

Chest deformities of long standing asthma are easily detected even with the patient fully clothed Not every asthmatic however, presents the same degree of chest deformity and the deformity varies with each type of individual in its time of onset as well as in its rapidity and extent of development The stature of the asthmatic sufferer is an important factor, the thin type showing chest abnormalities more readily than the obese type Moreover, in obese subjects and in women with large breasts deformities of the chest wall are difficult to detect by inspection alone since soft parts may completely mask the deformity In such cases radiological examination of the contour of the chest wall is very helpful The method I use is to outline the contour of the chest wall on an X ray film and to transpose it on a sheet of paper If the radiogram has been taken correctly, the outline of the chest will be clearly visible on the film, the edge of the ribs contrasting quite sharply against the shadow of less density given by soft parts covering the thorax

TABLE I

Ages of 82 Asthmatic Patients showing Chest Deformity

Age	Number of cases	Percentage
1–10 years 10–20 "	12 15 } 27	33
20–40 " 40–60 "	37 18 } 55	67

A radiological study of chest deformities has been made in a series of 128 consecutive and unselected cases of asthma attending the asthma clinic at the Leeds General Infirmary This paper does not deal with the more usual radiological signs of emphysema, such as localised brilliancy of the lung fields, increased density of the hilum shadows, and limitation of movements of the diaphragm From a recent discussion [1] it appears that radiologists now agree that the radiological diagnosis of emphysema must never be based on one sign alone but always on a combination One of the speakers, Dr Kerley, gave a timely warning that the so called increased translucency of the lungs may be due to factors which have nothing to do with the lungs Thus it can be produced by over exposure or over penetration, and it is also seen under normal technical conditions in thin subjects This is a point of some importance, for undue reliance on this very misleading radiological sign probably leads to the diagnosis of emphysema being made more often than is justified

TABLE II

Duration of Illness in 61 Cases showing Chest Deformity

Duration of illness	Number of cases	Percentage
0– 1 year 1– 2 years 2– 5 "	3 7 13 } 23	38
5–10 " 10–over "	21 17 } 38	62

It is somewhat surprising that in the radiological diagnosis of emphysema more attention is not paid to the appearances of the bony framework, for distension of the lungs must inevitably bring about deformity of the chest wall, and the degree of the deformity is therefore a good exponent of the amount of over stretching which has taken place in the lungs

In early cases the most noticeable change is a "ladder " appearance of the contour of the chest Normally the ribs which run obliquely from above downwards and forwards, overlap each other in a regular fashion, and with their outer surface form an even outline of the thoracic wall (Fig 1) As the lungs become over expanded the ribs become raised and approach the horizontal position, normal overlapping does not occur, the outer surfaces of the ribs fail to form an even contour, and the outline of the chest becomes irregular (Figs 2 and 6) This type of chest is often observed in asthmatic children and in adults with a short history of asthma In cases of longer standing a definite rounding of the chest takes place It is most noticeable in the upper part of the chest and affects mainly the six upper ribs one hemithorax may be more affected than the other so that the chest becomes asymmetrical. Often the over expansion is limited to a small area of the thorax and it may be localised to the upper or middle zones The intercostal spaces become wider in the over expanded part of the chest but the widening occurs in a very irregular fashion and not evenly from above downwards as it does in true hypertrophic emphysema. Thus over expansion of the lungs in asthma may select one part of the lung more than another *In cases with gross deformity* the thorax assumes the appearance shown in Figs 3 and 5 The upper part is rounded the ribs are raised and horizontal and the upper chest has a ballooned appearance At the level of the costal attachments of the diaphragm and especially at the level of the 9th and 10th ribs, the chest is drawn in and forms a deep lateral sulcus The lower part is unduly narrow and contracted This type of deformity is quite different from the so-called barrel chest of genuine hypertrophic emphysema in which the thorax becomes progressively wider from above downwards with a large inferior aperture and an obtuse subcostal angle (Figs. 4 and 7) In a barrel chest the outline as seen on a radiogram has the shape of a cone. A barrel chest is quite uncommon in bronchial asthma and was not found in more than 10 per cent. of cases in the present series of 128 cases. When it does occur it usually indicates the presence of true emphysema from chronic bronchitis or a pneumoconiosis

Thoracic deformities are commoner in adults than in children and their incidence increases after the second decade Thus of 82 patients showing such deformities 55 (67 per cent.) were over twenty years of age (Table I) Thoracic deformities occur fairly frequently in asthma and of the present series of 128 cases they were observed in 82 (65 per cent) In 14 there was very marked over-expansion of the chest 48 showed definite changes, while 20 showed *early and slight deformities* The degree of deformity was found to depend mainly on the duration of the illness and the frequency and severity of the attacks of asthma Cases of less than five years standing showed the lowest incidence (Table II) Occasionally however well marked chest deformities have been observed in patients with only a short history of asthma and this suggests the possibility of a hereditary predisposition to their development *Hajós*[2] found 16 per cent of the so called hereditary type of emphysematous thorax among 104 cases of asthma But it must be noted that these patients often have a long history of bronchitis during the anteparoxysmal stage Moreover the low percentage of such cases discredits the suggestion that asthma is the result and not the cause of the distended chest.

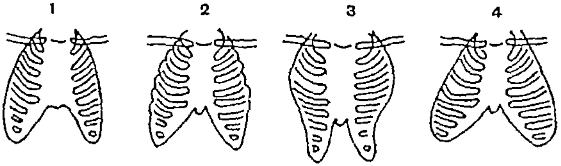

FIG. 1.—Normal contour of the chest.
FIG 2.—" Ladder " appearance of early type of chest deformity in asthma.
FIG 3 —Typical chest deformity in long-standing asthma
FIG 4.—" Barrel chest " of hypertrophic emphysema

SUMMARY

1 The chest deformity resulting from functional emphysema in asthma differs from the barrel chest of true hypertrophic emphysema

2 Early thoracic changes may escape clinical observation but are recognisable radiologically by outlining the contour of the chest on an X ray film

3 In a radiological study of 128 cases of asthma chest deformities were found present in 65 per cent of cases

4 The degree of deformity depends upon the duration of the illness and the frequency and severity of the attacks

REMOTE EFFECTS OF PUERPERAL SEPSIS

By MÉAVE KENNY, M R C S Eng, M C O G
LATE RESIDENT MEDICAL OFFICER QUEEN CHARLOTTE'S MATERNITY HOSPITAL ISOLATION BLOCK HAMMERSMITH

It is a widespread belief of the lay and medical public that puerperal sepsis is a uniquely crippling disease, with a train of physical, psychological, and eugenic ills Patients and their doctors appear to expect a long period of invalidism to follow the acute stage of a puerperal infection, and "considerate" behaviour is exacted from husband and relatives to far beyond the necessary or chivalrous measure

In this investigation of the remote ill effects of puerperal infection in 100 women treated in the isolation block of Queen Charlotte's Maternity Hospital, allowance has been made for the descriptions of malaise, neurosis or actual disability to be expected from women of a corresponding economic walk in life, even at ordinary post natal clinics Enough stress is not often laid on the fact that any practitioner observing cases in the first months of the post natal period cannot fail to receive complaints of bodily and mental impairment related to the confinement A woman bearing her child in the first year of married life endures the adjustments of marriage, pregnancy, and delivery in rapid succession She manages her household work until term, she is then tenderly treated in the maternity hospital during the lying in period, relieved of work and anxiety, and accustomed to a new high standard of life for a few weeks, and finally she is discharged to the burden of housekeeping plus the new, heavy, unremitting care of her baby Previously existing economic difficulties are increased by the new addition to the family, nursing is an added strain on the not completely readjusted organism Anxiety bred of unpractised mothercraft, loneliness after the congenial community of the lying-in ward, decreased opportunities to enjoy the common leisure of herself and her young husband because of the incessant needs of the child—all these are factors that must contribute to the want of well being suffered in the 12–18 months after childbearing by any woman of below a certain economic level of society, and all but a very few of my cases were drawn from such a class Adequate discount, therefore has had to be made for the natural reaction, both physical and psychical, from normality, exaggerated in my cases by the longer "holiday" in the isolation block, and the "rich living" that is a most necessary part of the successful treatment of puerperal sepsis

The causes of these disabilities cannot fairly be traced to the puerperal infection, nor is their remedy in the hands of the medical man

PROCEDURE

The scope of the inquiry was limited to a careful survey of the general health since the puerperal infection—noting the possible relation of any serious illness or operation to the original disease—the menstrual history the subsequent obstetrical history, and a general and pelvic examination

The material was derived from the files of the last few months of 1930, the whole of 1931, and the first month of 1932 arranged in Groups 1 to 5, according to the clinical history of the puerperal infection Four years had passed since the time of illness in most cases and in some nearly five years All the cases selected had suffered puerperal infection of more than average severity, their period of treatment in the isolation block had ranged from 4–5 weeks for septic endometritis without complications, to 12–14 weeks and over for peritonitis, cellulitis, or septicæmia, The great majority, as is usual in cases of such severity, had been infected with the hæmolytic streptococcus, which, with other pathogenic organisms, had been demonstrated bacteriologically in the genital tract, and/or the blood, peritoneal exudate, &c, according to the localisation of the lesion

For the purpose of this investigation 208 invitations to attend for examination were sent out, and 100 responses were received I examined all the cases personally

RESULTS

The results may be set out in tabular form as follows —

GROUP 1

Acute Septic Endometritis without Complications

Cases examined	22	Primiparæ	18	Average age 27½ years
		2 paræ	2	
		3 paræ or more	2	
General health good	22			

Serious illnesses (possibly related to puerperal infection)—	
Rheumatoid arthritis	1
Menstrual history—	
Normal	18
Dysmenorrhœa	2
Irregular	1
Menorrhagia	1*
Vaginal discharge—	
Slight, occasional	11
None	9
Continuous since infection	2
Subsequent pregnancies—	
None	20
Full term	1
Miscarriage	1†
General examination—	
Bones and joints rheumatoid arthritis	1
Pelvic examination—	
Nil abnormal	19
Cervicitis	2
Procidentia	1

* Hysterectomy for fibroids 1935

† 8 weeks Uterus emptied for therapeutic reasons unconnected with puerperal fever

GROUP 2

Pelvic Cellulitis with or without Thrombophlebitis Phlegmasia Alba Dolens, &c.

Cases examined	36	Primiparæ	26	Average age 26½ years
		2 paræ	8	
		3 paræ or more	2	
General health good	34			

Serious illnesses (possibly related to puerperal infection)—	
Rheumatoid arthritis	1
Pulmonary tuberculosis	1*
Menstrual history—	
Normal	26
Dysmenorrhœa	9
Irregular	8
Menorrhagia	0
Vaginal discharge—	
Slight, occasional	11
None	20
Continuous since infection	5†
Subsequent pregnancies—	
None	33
Full term	3
Miscarriage	0
General examination—	
Respiratory system abnormalities	1
Bones and joints (arthritis)	1
Pelvic examination—	
Nil abnormal	33
Uterine displacements	1
Residual thickening of ligaments	1†
Cervicitis	2†

* Treated and cured at Papworth

† One gonorrhœal being treated at Royal Free Hospital

GROUP 3

Peritonitis Diffuse 3; *Pelvic (including Tubal Masses)* 11

Cases examined	14	Primiparæ 2 paræ 3 paræ or more	8 3 3	Average age 28½ years
General health good	1[illegible]			
Serious illnesses (possibly related to puerperal infection)—				
Pernicious anæmia			1	
Menstrual history—				
Normal			11	
Dysmenorrhœa			0	
Irregular			2	
Menorrhagia			1	
Vaginal discharge—				
Slight occasional			8	
None			5	
Continuous since infection			1	
Subsequent pregnancies—				
None			14	
General examination—				
Circulatory system abnormalities (mitral incompetence)			1	
Nervous system abnormalities (disseminated sclerosis)			1	
Pelvic examination—				
Nil abnormal			10	
Tubal mass			2	
Cervicitis			1	
Ovarian cyst			1	

Same patient

GROUP 4

Septicæmia Complicating Endometritis Cellulitis &c

Cases examined	19	Primiparæ 2-paræ 3-paræ or more	15 3 1	Average age 27 years
General health good	17			
Serious illnesses (possibly related to puerperal infection)—				
Pulmonary tuberculosis			1	
? Glandular fever			1	
Rheumatic fever			1	
Quinsy			1	
Menstrual history—				
Normal			19	
Dysmenorrhœa			0	
Irregular			0	
Menorrhagia			0	
Vaginal discharge—				
Slight occasional			11	
None			8	
Subsequent pregnancies—

Treated and cured at Brompton Chest Hospital.

GROUP 5

Acute Septic Endometritis with Complications, Urinary Tract Infection, Pulmonary Infection or Infective Arthritis

Cases examined	9	Primiparæ 2 paræ 3-paræ or more	5 4 0	Average age 26½ years
General health good	8			
impaired	1 (septic arthritis with marked deformity of hands improving slowly with treatment)			
Serious illnesses (possibly related to puerperal infection)			0	
Menstrual history—				
Normal			7	
Dysmenorrhœa			2	
Vaginal discharge—				
Slight occasional			5	
None			1	
Continuous since infection			3	
Subsequent pregnancies—				
None			9	
General examination—				
Bones and joints; septic arthritis			1	
Pelvic examination—				
Nil abnormal			6	
Uterine displacement			1	
fibroid			1	
Procidentia			1	

Certain *extragenital morbid conditions* were uncovered during the investigation

Rheumatoid Arthritis (3 cases) —These patients had well marked lesions All were receiving treatment for the condition at various hospitals and admitted relief All had had hæmolytic streptococcal puerperal infection One with severe deformity of fingers and wrists had developed the arthritis during the course of the puerperal fever The others within two years after discharge from the isolation block.

Rheumatic Heart Disease (2 cases) —Both showed signs of mitral disease with fairly good compensation. One aged 22 had had an attack of rheumatic fever nearly two years after the hæmolytic streptococcal puerperal infection (septicæmia) The other had shown no sign of a cardiac lesion during her period of treatment at the isolation block, but described having had chorea in childhood. The puerperal infection in her case had been an acute endometritis and pyelitis the infecting organism being predominantly *Bacillus coli*

Pulmonary Tuberculosis (2 cases) —Neither had shown signs of lung disease at the isolation block. One developed phthisis in the second, and the other in the third year after discharge Both received sanatorium treatment and are free from active symptoms They had been warned against pregnancy and instructed in correct contraceptive procedure.

Disseminated Sclerosis (1 case) —The history suggests that the disease began in adolescence and is pursuing the expected course

DISCUSSION

It was hoped that this investigation would throw valuable light on the damage and deformity that might be expected as a residue of severe infection of the genital tract It is seen however that the pelvic findings are on the whole negative, and not fairly to be held responsible for the rather wretched and gynæcological aspect of most of the women that I examined.

A notable number of cases in every group showed no gross lesion of the pelvic organs After careful examination per speculum and bimanual, 87 cases had no evidence of tubal masses, uterine displacements cervicitis or vaginitis

Cervicitis was present in 5 cases only and this is remarkable when one considers how often severe pelvic cellulitis accompanies deep tears of the cervix One case was frankly gonorrhœal

Tubal or tubo-ovarian masses were found in 2 cases both in the pelvic peritonitis group In one of the cases during treatment in the isolation block, there had been reason to suspect an antenatal tubal affection It is possible that the distinctly thickened tube now palpable is a relic of that state rather than of the puerperal infection. The other patient complained of backache dysmenorrhœa, and a dragging pain on the side of the tubo-ovarian mass some days before the monthly period Neither had conceived again

Fixed retroversion with no other lesion or symptom was found in 2 cases, one of whom had carried a pregnancy to full term eighteen months before examination Procidentia likewise was present in 2 cases One patient an elderly and multiparous woman had had a child since the puerperal fever and dated the prolapse from this later pregnancy The other a flaccid atonic creature who had had a severe second-degree tear at the delivery of her first and only child, and was repaired six months after discharge from the isolation block, complained of stress incontinence, and had a well marked vesicocele and rectocele

As the investigation proceeded therefore my interest was narrowed upon what was emerging as the most appreciable abnormal residuum of the original puerperal infection in the large majority of the cases examined—namely sterility *Among 100 women during 4–5 years of the active childbearing* *period, there had been only 5 pregnancies and only 4 live births*

Failure to conceive may of course be conditioned by a number of factors other than damage to the reproductive tract by puerperal sepsis, and in view of the largely negative findings under that heading, these other factors were examined under three headings

(a) *Contraceptive measures* were found to be widely but haphazardly employed The methods used to check conception ranged from the complete abstinence of one patient (a woman on the verge of dementia præcox) through quinine pessaries, coitus interruptus, "safe period" intercourse, to obstructive appliances of more or less efficacious type Of the 95 "sterile" women, 26 had used no contraceptive whatever, 9 being anxious to conceive because of the loss or the loneliness of an only child, the remainder were indifferent to the possibility of pregnancy, but on the whole inclined to enjoy the accident of sterility Of the 69 women using contraceptives, only 22 could be described as using their chosen methods with the care or discretion necessary for success The rest relied on measures that in the normal woman largely fail to protect against conception, or used these only now and again

(b) *The interval that may be supposed normally to elapse between pregnancies* was estimated from a 'control" group of 38 multiparous women, of roughly comparable age and social (economic) level, treated in the isolation block during the past five months It was found that the average interval between the first and second child is $2\frac{2}{3}$ years, and between the second and third $3\frac{1}{2}$ years The extremes in the group were 7 years in one case, and 11 months in two

(c) *Subsequent pelvic infection* —One patient acknowledged and showed clinical evidence of a gonorrhœal infection contracted since the puerperal fever She had a chronic cervicitis and bilateral tubal masses

Excluding the cases dealt with in these categories, there remained the large number of women who in the absence of gross pelvic lesions remained infertile for 4–5 years following a severe puerperal infection These were more closely examined

Of the 9 women anxious to achieve pregnancy, 7 fell into Group 3, the "peritonitis (pelvic and diffuse)" group, which thus appears to be the least residually fecund if one excludes Group 4, the septicæmia group of 19 patients who one and all desired no repetition of their childbearing experiences, and appeared to be, with few exceptions, "ladies that have intelligence in love" sufficient to avoid its consequences Fallopian tube involvement is probably most commonly found as the result of peritonitis, and only unusually of extension by direct continuity from an acute septic endometritis It is often impossible to diagnose tubal masses in the acute stage of puerperal infection if they are associated with peritonitis, and, in this investigation, have been classed in the peritonitis group when suspected clinically Probably permanent sterility is most likely to occur in this group although the absence on examination of palpable evidence of tubal damage remains a fact that somewhat disturbs this conclusion And it is only equally plausible to argue that sealing of the uterine end of the tubes in the course of a septic endometritis as apart from the endosalpingitis of a gonorrhœal infection, happens very frequently, and is the cause of sterility in such cases

It is fascinating to speculate on the results of lipiodograms to test the tubal patency of such a series of sterile women and in the absence of such research the causes of the widespread sterility uncovered in my investigation must remain a matter of hypothesis only

SUMMARY

1 Some psychical and physical debility is a common post natal finding in women living at a low economic level

2 Complete restoration to normal health may be expected for the large majority of women recovering from severe puerperal infection

3 Some morbid conditions uncovered during this investigation appear to bear a close relation to the original puerperal infection, notably rheumatoid arthritis and mitral valvular disease

4. This investigation shows that sterility is a prominent sequel to puerperal infection It is not an invariable result, and must be described as dependent to some extent upon extrinsic factors such as subsequent pelvic infections, the "natural" interval between pregnancies, and the wide dissemination of contraceptive knowledge among the population In the absence of any general evidence of gross pelvic damage, it is not possible to relate the sterility to any specific lesion of the genital tract

I wish to acknowledge my indebtedness to Dr Leonard Colebrook who encouraged this investigation, and to the members of the honorary staff of Queen Charlotte's Maternity Hospital who kindly allowed my use of case records, and gave me helpful advice on procedure, deductions, &c

---

THE THERAPEUTIC ACTION OF p-AMINOBENZENESULPHONAMIDE IN MENINGOCOCCAL INFECTION OF MICE

By H Proom, B Sc, A I C

(From the Wellcome Physiological Research Laboratories, Beckenham, Kent)

Buttle, Gray, and Stephenson (1936) have reported in this journal that p aminobenzenesulphonamide protects mice against experimentally induced meningococcal septicæmia The degree of protection, and the most suitable method of administering the drug, have now been more fully investigated

TECHNIQUE

Infection of mice—Mice were infected with virulent meningococci according to the method described by Miller (1935) and more fully by Miller and Castles (1936) Strains were kept on a phosphate buffered meat infusion agar medium similar to that described by Miller (1935), they were subcultured daily, and a five to six hour culture was used for infection The culture was removed from the slope with a wire loop, suspended in physiological saline and adjusted to an opacity corresponding to one thousand million organisms per c cm A tenfold dilution was made in 5 per cent mucin suspension, from which further culture dilutions also in mucin suspension were made on a one hundred fold range The mucin used was Granular Mucin (hog's gastric) obtained from the Wilson Laboratories, Chicago other brands were tried and found unsuitable A 5 per cent suspension in distilled water containing 1 per cent glucose was sterilised by steaming and adjusted to pH 7 3 with normal sodium hydroxide and used as the suspending fluid The meningococci were injected intraperitoneally into mice in 1 c cm of mucin suspension the injections being performed within half an hour of the preparation of culture dilutions

Administration of drug—The drug has been given subcutaneously and by the mouth The subcutaneous injections were made with a 2 per cent solution of the drug in distilled water it being necessary to warm to about 40° C in order to effect solution at this concentration A 10 per cent suspension of the drug in distilled water containing approximately 3 per cent gum acacia as a stabilising agent was used for oral administration. Intraperitoneal injection was not used owing to the higher toxicity of the drug when given by this route and intravenous injection was not suitable for amounts greater than 10 mg owing to the low solubility of the drug (2 per cent. at 37 C)

EXPERIMENTAL

Mice infected with a mucin suspension of virulent meningococci die from a meningococcal septicæmia within three (usually two) days the time of death depending upon the number of infecting organisms The appearance of mice dying from meningococcal infections has been described by Miller and Castles (1936) and is similar to that of mice dying from streptococcal or pneumococcal infections no symptoms indicating meningeal involvement being observed

Degree of protection obtained with p-aminobenzene sulphonamide —Table I shows the protection obtained with *p* aminobenzenesulphonamide against varying numbers of meningococci of a virulent Group II strain the drug was given in different amounts by the subcutaneous and oral routes

It will be seen that the drug will protect against a million lethal doses of meningococci when it is given under optimal conditions as in Experiment No 8 In this case 7 out of 10 mice infected with one hundred organisms died and all the treated mice receiving one hundred million organisms survived There is little difference in the degree of protection obtained when the drug is given by the oral or subcutaneous route Protection has never been observed against a dose of one thousand million organisms

The most suitable dose of *p* aminobenzenesulphonamide appears to be 10 mg subcutaneously or 25 mg orally given immediately and repeated five and twenty four hours after the injection of organisms

TABLE I

Showing protection obtained against the same strain with various doses of p-aminobenzenesulphonamide given subcutaneously and orally

Numbers indicate mice surviving one week out of groups of ten mice injected

Treatment.	Treated			Untreated controls				Mucin controls.
	Number of organisms injected—							
	10T	M	100M	100	10T	M	100M	—
(1) 10 mg subcutaneously immediately after injection of organisms	10	10	6	2	2	0	0	10
(2) 10 mg subcutaneously immediately and 5 hours later	10	10	7	2	0	0	0	10
(3) 10 mg subcutaneously immediately and 18 hours after	10	0	7	6	2	0	0	10
(4) 10 mg subcutaneously immediately 6 hours later and on two successive days	10	10	0	8	2	0	0	10
(5) 5 mg immediately and 5 hours later	10	7	2	[illegible]	3	0	0	10
(6) 5 mg orally immediately	10	8	0	3	0	0	0	10
(7) 25 mg orally immediately and 5 hour later	10	10	6	1	0	0	0	10
(8) 25 mg orally immediately 5 hours and 24 hours later	10	0	10	3	0	0	0	10
(9) 50 mg orally immediately and 5 hours later	7	9	6	1	0	0	0	10

10T = 10 000
M = 1 000 000

With larger doses of the drug the combined action of drug and mucin makes the mice very ill, and a few fail to recover Mucin alone has little effect on the mice

Meningococci can be isolated from the blood of all the untreated animals which die but it is seldom possible to isolate meningococci from the blood of moribund treated animals which have received an infecting dose of not more than one hundred million organisms This probably indicates that in the case of the few treated animals which die the course of infection has been checked although their resistance has been so lowered that death ensues even in the absence of septicæmia In isolating meningococci from the blood the technique described by Miller and Castles (1936) has been followed

TABLE II

Showing the protection obtained against the same strain when the first dose of drug was given immediately two five and eighteen hours after the injection of organisms

Numbers in table indicate mice surviving out of groups of ten

Treatment	Treated			Untreated controls				Mucin controls
	Number of organisms injected—							
	10T	M	100M	100	10T	M	100M	—
25 mg orally immediately repeated 5 and 18 hours later	10	0	10	3	0	0	0	10
25 mg orally 2 7 and 20 hours after infecting organisms	10	8	1		1	0	0	10
25 mg orally 5 18 and 23 hours after infecting organisms	7	6	0	0	0	0	0	10
25 mg orally 18, 3, and 30 hours after infecting organisms	1	0	0	1	1	0	0	10

It is not necessary to keep mice under observation for more than a week for late deaths due to meningococcal infection do not occur Treated mice have been kept under observation for a month and remained quite healthy

Effect of giving the drug at various times after the injection of meningococci —A very much lower degree of protection is obtained if the administration of the drug is delayed for a few hours Table II shows the results obtained when the course of injections of the drug was started immediately and two five, and eighteen hours after the injection of organisms.

When the drug was given immediately after the injection of culture almost complete protection was obtained against varying numbers of meningococci up to one hundred million organisms. If the administration of the drug was delayed for two hours no protection was observed against an infecting dose of one hundred million organisms It was observed that blood cultures from these mice which were not protected were positive before the drug was given Good protection was obtained against an infecting dose of ten thousand and a million organisms The blood cultures from these mice were negative before the injection of the drug A much poorer protection was obtained if the giving of the drug was delayed for five hours and by this time the blood culture from most of the mice had become positive A few of the mice having a positive blood culture were protected by the drug No protection was observed if the administration of the drug was delayed for eighteen hours By this time a number of mice were dead or moribund, and the blood cultures from all living mice were positive

Protection against different strains —The protective action of the drug has been tested against six different strains of meningococci , the results have been summarised in Table III It appears that the drug protects equally well against strains belonging to Group I and Group II

TABLE III

Showing protection obtained with six different strains of meningococci All mice received 25 mg orally immediately, five, and eighteen hours after injection of organisms

Numbers in table indicate mice surviving out of groups of ten

Strain	Group	Treated			Untreated controls				Mucin controls
		Number of organisms injected—							
		10T	M	100M	100	10T	M	100M	—
M 393	I	8	10	6	10	2	0	0	10
M 398	II	10	10	6	9	8	3	1	10
M 406	I	10	10	3	7	1	0	0	10
M 407	I	10	10	5	8	6	0	0	10
M 409	II	10	10	6	4	0	0	0	10
M 410	II	10	9	10	3	0	0	0	10

Comparison of the type of protection obtained against streptococcal and meningococcal infection in mice —In view of the fact that the effect of *p* aminobenzene sulphonamide on streptococcal infection in mice has been extensively studied, some comparison of the protection obtained against this organism and against the meningococcus appears desirable Buttle, Gray, and Stephenson (1936) have shown that with streptococcal infection of mice, protection can be obtained against ten thousand lethal doses of a highly virulent strain this protection being independent of the Griffith type of the streptococcus Also, in order to obtain complete protection, the drug must be given daily for fifteen days after the injection of organisms As Levaditi and Vaisman (1935) state that streptococci survive in the spleens of treated mice up to the eighth day after infection it seems probable that this continued administration of the drug is necessary to eliminate these localised organisms and prevent them setting up a generalised septicæmia Nitti and Bovet (1935) have shown that it is not possible to protect against large numbers of organisms of a comparatively avirulent strain of streptococcus

With the meningococcus a slightly higher degree of protection is obtained—namely, under optimal conditions against a million minimal infecting doses of organism It is unnecessary to continue the administration of the drug for several days, possibly because the meningococcus unlike the streptococcus, is incapable of establishing a local focus of infection As with the streptococcus, protection is obtained equally well against organisms of different serological types and it does not appear possible to protect against more than a certain number of organisms, irrespective of the virulence of the strain

DISCUSSION

The foregoing experiments show that the early oral administration of *p* aminobenzenesulphonamide prevents the development of septicæmia and death in mice infected with meningococci. In man the spread of infection from the nasopharynx to the meninges is most probably via the blood stream, the prophylactic use of the sulphonamide in epidemics seems, therefore, worthy of consideration

There is some evidence that *p* aminobenzene sulphonamide administered orally reaches the cerebro-spinal fluid *p* Aminobenzenesulphonamide as shown by Colebrook, Buttle, and O'Meara (1936) inhibits the growth of streptococci in blood and culture medium It has been found that the cerebro spinal fluid taken from rabbits which have received large doses of the drug inhibits the growth of a small inoculum of streptococci whereas a similar number of streptococci grow freely in the normal fluid (To facilitate growth, a little human blood is added in both cases)

In established cases of meningococcal meningitis in man the conditions may not be comparable with those following intraperitoneal injection of culture into mice The results of the mouse experiments, however, together with those obtained with the cerebro spinal fluid in rabbits, suggest a clinical trial of *p* aminobenzenesulphonamide even when meningeal involvement has already occurred

SUMMARY

1 *p* Aminobenzenesulphonamide given immediately after infection protects mice against approximately a million minimal infecting doses of meningococci

2 Protection is equally effective against Group I and Group II meningococci

3 When the administration of the drug is delayed for several hours after the injection of organisms a much lower degree of protection is obtained

My thanks are due to Dr G A H Buttle and Dr H J Parish, under whose guidance this work was carried out

THE PLASTER BED

BY F P FITZGERALD, M.B Dub , F R C S Irel.
AND
K I NISSEN, M.D N Z , F R C S Eng
HOUSE SURGEONS TO THE ROYAL NATIONAL ORTHOPÆDIC HOSPITAL STANMORE MIDDLESEX

THE making of plaster beds is such an ordinary part of surgical practice that the description of any method calls for some explanation. This is to be found in the fact that although the technique to be described is not original, and has long been in use at a few hospitals besides the Royal National Orthopædic Hospital, we think that its merits deserve wider appreciation The method is usually attributed to Prof J Waldenström of Stockholm, but in a personal communication from him we learn that while it probably reached England from his clinic, he himself first saw it employed by Calot at Berck sur mer

MATERIALS

1 Plaster muslin, 32 threads to the inch (a material of constant quality may be obtained from the Stanmore Cripples Training College) Ten to twelve doubled sheets

ON WRITING FOR THE LANCET

JUST as the motorist is sometimes a pedestrian so the writer is sometimes a reader For this if no other reason we ask him to look at our Contributors Code whose general observance—though it contains nothing new to some careful drivers—would reduce casualties and free the editorial police for more useful duties

LENGTH

Short papers are more likely to be read and more likely to be published But papers can be long at 500 words and short at 5000 according to their material The secret of brevity is repeated revision the author's best friends are a month's delay and several candid critics

LANGUAGE

Every sentence should be *as simple as possible* apart from technical terms it should be intelligible at a first reading to any educated person The pompous circumlocution often thought appropriate to scientific publications is an enemy to clear thinking and an obstacle to the spread of information among busy practitioners The modern article written in medical jargon instead of English is apt to begin something like this —

> Though numerous instances have been recorded in the United States examination of the literature with reference to idiopathic glandulosis suggests that this disorder is of relatively infrequent occurrence in this country Up to the present time no consensus of opinion exists in connexion with the factors which may play an ætiological rôle in its causation, and in view of their variety taken in conjunction with certain abnormal characteristics involved in their symptomatology it would appear that the following series of cases under the present author's observation may be of sufficient interest to warrant being placed on record.

Given time we might translate it thus —

> Though often reported in the United States, idiopathic glandulosis appears to be less common in this country Its cause is still uncertain and I am recording these cases because the disease is rare and some of the symptoms were unusual.

The stigmata of jargon include over use of words with abstract meanings (*of a blue coloration* rather than *blue*) of the passive voice instead of the active (*it is believed by Smith* instead of *Smith believes*) of long words or constructions usually Latin in origin instead of short ones (*subsequently to* rather than *after*) For an analysis and righteous condemnation of these and similar practices we refer those interested to Lecture V of Quiller Couch's Art of Writing (Cambridge University Press) Meanwhile, though admitting the insecurity of people who live in glass houses we offer examples of overworked or misused words and phrases marking some of the most tiresome with an asterisk and suggesting alternatives

a degree of *some*
*ætiological factor *cause*
as a result : *hence*
a variety of *many various*
*case : *patient child man*
certain : *some*
commence *begin*
consider : *think hold believe*
considerable *much large high*
employ : *use*
exists : *is*
experimental dog *dog*
extensive : *big long*
fifty per cent *half*
following the *after the*
frequent : *common*
*frequently *often*
indicate *show suggest*
indication : *sign*
*individual *person man woman cat*
*in few instances : *seldom*
in large measure *largely*
in regard to : *about*
in the case of : *in*
invariably *always*
majority of *most of*
*marked *much great, big obvious evident*
meticulous : *careful elaborate*
nature *kind sort*
numerous : *many*
*occur *happen appear develop arise*
one-half *half*
pathology : *disease abnormality*
portion *part*
practically *almost*
previous to : *before*
prior to : *before*
prolonged *long*
psychological *mental, emotional*
regarding *about as to*
render *make*
state *say write*
subsequent to : *after*
symptomatology *symptoms*
theory *opinion idea*
to some extent *somewhat*
would appear *seem appear*

Such favourites as *etc literature, phenomenon respectively stressed* and *tendency* can often be omitted with advantage. And even scientific caution should have bounds : *apparently* is as good as *I cannot disguise from myself that it would appear that*

We are sometimes asked in accepting an article to add where necessary a few journalistic touches But nowadays it is the layman not the journalist who writes journalese Leading articles in the popular press are usually models of straightforward English

MODESTY

The first person singular—the naked *I*—is no longer thought immodest Elaborate garments such as *we* and *the author* do not disguise a writer's identity unless they also disguise his meaning and medicine has no need of such aids to ambiguity Not only the author's name should be given at the head of the paper but also his decorations, his degrees and their source and relevant diplomas A statement of one *or more appointments is preferable in a general* medical journal to the vague formula From the ——— Institute

ANONYMITY OF PATIENTS

The patients identity on the other hand must always be hidden If in distinguishing between several of them it is convenient to use initials, the conventional *A B* or X Y may be used No recognisable portrait will be reproduced without written permission from the patient or his friends

PRESENTATION OF MS

Papers should be submitted in typescript if possible but carbon copies are disliked by all editors and single spacing should not be used except for quotations (Really accurate reproduction of quoted passages is rarely achieved but is undoubtedly desirable) Paragraphs that may suitably go into small print should be marked with a vertical line in the margin these will usually include —

1 Case notes (which may be written tersely)
2. Descriptions of technical methods ;
3. Parts of the paper that can be skipped by the ordinary reader because they are not essential to the argument
4 Lists that require the greater prominence given by separate paragraphing (Nos 1–4 here are an example)

But the use of numbered lists reminiscent of examination answers can certainly be overdone Shakespeare if a surgeon would probably have written

(1) To be or (2) not to be that is the question
Whether tis nobler (3) in the mind to suffer

Information about headings, and form in general, is best gained by studying papers already published. Two kinds of cross heading are used in THE LANCET—the "lower case bold" and the "small caps"—but the former is ordinarily avoided except in long articles. Side headings, unless they are headings for cases (e.g., CASE 3) are in italics, and may take one of two forms:—

Further History.—The patient went from bad to worse.
The *further history* was disappointing.

Long sections in small type can be divided by small type cross-headings.

ITALICS

The significance of italic headings is lessened by lavish use of italics for other purposes. Subsidiary italic headings inside a paragraph are therefore inconvenient, and words like "post mortem" and "in vitro" have now become English and need no longer be treated as foreign bodies. The same applies to the everyday names of animals and vegetables, in Latin or English. In THE LANCET neither capitals nor italics are adopted in:

The felidæ, and other mammalian genera, are susceptible alike to ascaris and staphylococcus.

Nor is it thought wise to apply italics to semi-slang, like *B. Pfeiffer* which can equally well be rendered as "Pfeiffer's bacillus." But (whatever the particular classification) the proper scientific names, which give both genus and species, are always italicised, with an initial capital for the genus only and a distinguishing name added where necessary:—

Bacillus welchii, *Bacterium dysenteriæ* Flexner, *Brucella abortus* Bang, *B. paratyphosus* B.

When the generic name is first mentioned it should be spelt out (*Bacillus tuberculosis*), but afterwards the contraction *B. tuberculosis* will serve.

TABLES AND ILLUSTRATIONS

Tables, which will always be printed in smaller type, should be numbered in roman numerals and put on sheets separate from the text. The printer cannot always place them exactly where the author intends, and hence one must say "the results are given in Table VI" rather than "the results were as follows." An exception may be made for very short Tables and those that can be split without harm if they happen to start near the bottom of a column. Illustrations, too, should be kept separate from the text, being numbered consecutively in arabic numerals (Fig. 1, Fig. 2, &c.), whether they are charts, photographs, or drawings. Each Figure should have a reference in the text, and preferably a descriptive legend to be printed underneath. Since the lettering of charts and drawings often proves unsatisfactory when the illustration is reduced in making the block, the Editor is prepared to arrange for completion of illustrations whose lettering is done in pencil. When graph paper is used for charts the ruling should not be brown, red, or green, which come out black. The magnification of microscopical illustrations ought to be stated (e.g., × 150).

SUMMARIES

Conclusions and summary may often be combined. They are helpful to all but very short papers and should be carefully constructed because many readers abroad (and some at home) will look at nothing else. Here are examples of the descriptive summary (A) which is almost useless, and the informative summary (B), which will be reproduced or translated all over the world:—

A. A series of cases of food poisoning is reported and their causation discussed.

B. Fifteen people fell ill with vomiting an hour after eating lizard soup. Skin tests showed that they were hypersensitive to lizard.

ABBREVIATIONS AND "LANCET" STYLE

Contracted forms like *T.B.*, *C.S.F.*, *R.B.C.*, *B.M.R.*, *M.L.D.* must be either eschewed or explained when first used. *Grains* and *grammes* should be spelt out in full where there is any conceivable chance of confusion; otherwise THE LANCET convention is *gr. 2* for two grains and *2.0 g.* for two grammes. Other abbreviations are:—

cm.	kg. (not kilo)	ml.
c.mm.	kv.	oz. (not ozs.)
c.cm. (not cc.)	lb. (not lbs.)	*p*H
ft.	µ	sp. g.
in. (not ins.)	mg. (not mgm.)	sq.

Dates.—Nov. 10th (not 10 Nov. or 10.xi.36). 1933–35, not 1933–5.

Numbers.—Should numerals or words be used? The best rule is that comparable numbers should be in the same form, and the two styles can sometimes be contrasted usefully—e.g., "No less than 4 of the 42 patients were under fourteen years of age." But a numeral must never begin a sentence. Nor can decimal points be left in the air: *0.5* is correct, not *.5*.

Every journal has sundry preferences or prejudices. Ours include:

Graves's disease, not Graves' or the commoner Grave's. Mg. per 100 c.cm., not mg. per cent. Per cent. not % (except in Tables). Aged, not aet. A radiogram and to radiograph, not an X ray or to X ray. Post mortem (adverb), post-mortem (adjective or, loosely, noun).

REFERENCES

Lists of references are not required merely as evidence or erudition. If given they must be above suspicion: to take over a reference from someone else without verification or acknowledgment is a crime. Each reference, moreover, should give the author's name and initials, the year of publication, the name of the journal cited (contracted henceforth according to the current edition of the "World List of Scientific Periodicals"), the volume (underlined), and the number of the first page of the paper. For books the place of publication is stated but not the publisher's name. References are now made by giving in the text the name of the author and the date of publication, thus—

This is disputed (Jones 1936) but

Wrong headed as ever, Jones (1934) maintains

If Jones has written more than one paper in the year they should be distinguished as *a*, *b*, &c., and space can be saved by saying *and others* when teams of workers are quoted repeatedly.

The work of Jones (1935a) was soon dismissed (Wong, Fairbanks, Hepburn, and Loy 1936, Hulbert 1936b) and it was found that rhubarb is useless (Wong and others 1937).

The list of authors quoted is now put at the end of the article in alphabetical order; but if need be the items can be numbered so that the writer may say "it has been shown[12, 14, 26, 53] that cows eat grass" without interrupting the text with a dozen names of little immediate interest. The following examples show the use of short rules to represent names that are repeated, and of *Ibid* to represent the book or journal mentioned in the previous line. (*Loc. cit.* and *op. cit.* are not acceptable.)

Brown, A., and Smith, B. (1939a) *J. med. Conchol.* 34, 3000.
— — (1939b) *Ibid*, 35, 1608.
— — and Dogsbody, D. (1940) Epidemiology for Oysters, London, p. 9.
— — — and Robinson, E. (1941) *Lancet*, 1, 1000.
— (1942) *Ibid*, 2, 2784.

The "World List" is published by the Oxford University Press at £3 3s. Contributors who have no access to it and cannot find the abbrevi n they want in the following selection are asked t ive the full names of journals quoted and mark th in the margin with a pencil cross

PUBLISHED BY THE PROPRIETORS THE LANCET LIMITED 7 A t Adelphi, the County of London
and printed by HAZELL, WATSON & VINEY LTD 52 L —Saturday nuary 2 1937

of this are cut beforehand to the patient s measurements—i e for a bed, the patient is measured from the nasion over the vertex to halfway down the calf for an anterior shell from the nasion to halfway down the calf In either case the width is the distance between the tips of the elbows when the arms are abducted to 90°

2 Plaster-of Paris, 10 lb (Torrey s superfine Italian)

3 A basin holding 12 pints of water at 120° F and an iron spoon for mixing

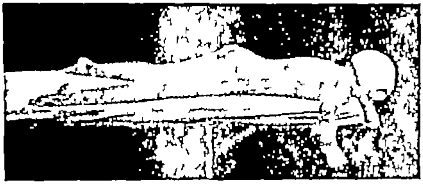

FIG. 1.—Position for plaster bed

4 A table of suitable height covered by a rubber mattress

5 Vaseline 2 in open wove bandages and cotton wool.

6 An adjustable theatre stool and sandbags

7 Scalpels for outlining and knives (linoleum knives with concave blades and wooden handles) for cutting out the cast.

PREPARATION OF THE PATIENT

For a plaster bed the patient lies prone on the table, with the chin resting on the edge arms abducted to 45 and each leg abducted *to 15 (Fig 1).*

For an anterior shell the patient lies on his back with legs and arms arranged as for a bed. The neck is allowed to hyper extend over the edge of the table until the under surface of the chin is horizontal (Fig 2) The head is supported in this position by a sandbag resting on the adjustable stool, and the face is covered with a sheet of gauze. A capeline bandage, or a rubber cap completely covers the hair and in the case of a plaster bed pads of wool over the ears are included to make the finished headpiece more roomy A very thin layer of vaseline is smeared over the skin down to the middle of the calf and a minimum of wool used to cover the pubic and perineal regions.

PROCEDURE

A team of five, *familiar* with their parts, is the ideal, but the number may be reduced to three. The first assistant makes the plaster cream by adding the 10 lb of plaster powder to the 12 pints of hot water and then whipping the mixture to an even consistency with the spoon. The second assistant hands successive double sheets by their folded ends to the first assistant, who dips them thus into the cream. The sheets now like ropes, are lightly stripped of excess cream and are handed quickly and *still* by the folded ends to the other three assistants who are disposed about the table as follows the third stands at the head of the patient, the fourth and fifth on either side of him near the knees The three open out the sheet pull it taut to remove creases (Fig. 2) let *it fall squarely on to the patient* and then smoothe away air bubbles from the midline outwards The fourth and fifth assistants as each sheet is laid press it firmly down to the table between the thighs and perineum so forming a flat bridge connecting the gutters *for the legs The excess muslin* —except in the first and last sheets which determine the internal and external finish of the cast—is folded back at the level of the knees on to the thighs At the sides the sheets must not be moulded under the *patient as this would cause* difficulty in removing the cast. For children it is unnecessary to strengthen the sides by folding back the excess but for adults every second sheet should be so treated

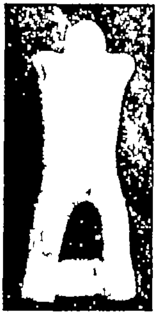

FIG. 4.—Finished anterior shell before mounting

If a bed is being made the *third assistant standing at the* head folds back the excess of the eight to ten intermediate sheets at the vertex and in front of the ears moulding it accurately to the back and sides of the neck. If a shell is being made the intermediate layers are folded back along the symphysis and rami of the mandible, and moulded back along the front of the neck to form a strong horizontal *chin piece The assistants then wash their hands* free of crumbs of plaster and produce a good finish by firmly smoothing the cast from the centre outwards to eliminate air bubbles.

Speed is essential for a good result as the warm plaster cream sets very quickly The procession of sheets must follow without break and all must have been laid within at the most five minutes The *cast is now allowed to set (Fig. 3) until it gives a*

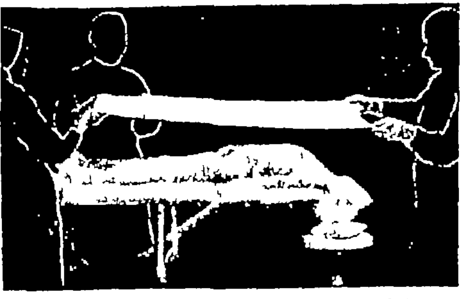

FIG. 2.—Position for anterior shell laying on the first sheet

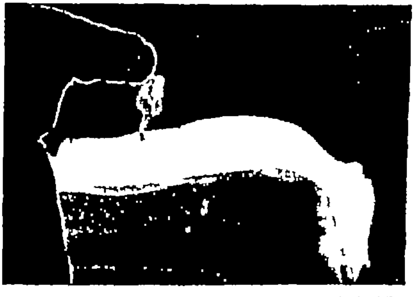

FIG. 3.—Outlining the nursing area of an anterior shell while the cast is setting

high pitched note on tapping While this is happening, the outlines are marked with a sharp scalpel, the sides an inch from the table level, the shoulders in line with the sides, and the upper and lower edges at the level of the folding back An area for nursing purposes is outlined (Fig 3), extending in a bed from the top of the natal cleft, or in an anterior shell from an inch above the pubic crest (Fig 4) to midway between the perineum and the knee on either side, exposing one third of each thigh In a bed, care is taken to make the opening a pointed arch so that the buttocks are adequately supported. When the cast has set, it is eased off all round by insinuating a hand between it and the table, and is then taken to another table where the outlines already marked are quickly cut through with the knives described. It is then tried on the patient (Fig 5) and any necessary trimming carried out From start to finish the whole proceeding should take not more than fifteen minutes The cast is dried for two days in a heated room When thoroughly dry, it is mounted by a carpenter on three shaped transverse supports of 1 in timber, high enough to allow the easy insertion of a bed pan These uprights are affixed by countersunk screws at the neck, lumbar region, and above the knees, and joined by two lateral 3 in strips of three ply wood giving a considerable area for contact with the mattress (Figs 6 and 7) A loose lining is made of linen sheeting and thin blanket sewn together along the edges, having an area cut out to correspond to the nursing area of the plaster cast, and held in position by tapes

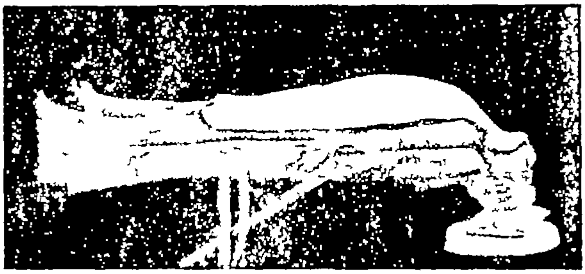

FIG 5 —Trying on an anterior shell after trimming

FIG 6 —Method of mounting

MODIFICATIONS

The bed and shell described are the standard types in use at Stanmore, but many modifications are possible

1 In cases of spinal disease when the lesion is below Th 6 the headpiece may be omitted from a bed , in high lesions the head is always included

2 In active children movements may be restrained by means of a wooden crosspiece shaped to the chin and bolted to two uprights (see Fig 8)

3 When a kyphosis exists at the scapular level, a quadrilateral area may be cut out of the plaster bed and local pressure applied by a split Sorbo pad mounted on a wooden tower This is pushed through the cut out area to rest against the spine above, and supported by a cross board on the firm mattress below

4 A sharp kyphos can be protected by pads of Sorbo glued to the inside of the bed

5 For adults, anterior shells may be made without chin pieces, but children find these comfortable, especially for reading

6 For cases with profusely discharging abscesses, areas should be cut out to allow free postural drainage

7 For thin patients, particularly when paraplegic, areas may be cut out to expose the anterior superior spines and iliac crests

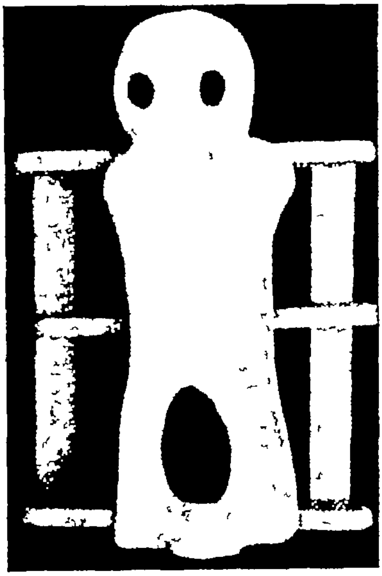

FIG 7 —A plaster bed from above showing supports (wider than usual) and ventilation holes in the headpiece.

8 For ease in transport, the three ply laths may be replaced by longer two by two inch timber with the ends fashioned as handles

9 Turning cases for use with plaster beds may be made as for a very shallow anterior shell without chin piece or bridge

INDICATIONS FOR USE

PLASTER BEDS

1 Tuberculous spines in adults

2 All cases with paraplegia

3 Abdominal paralysis in anterior poliomyelitis

4 Some cases of fracture of the spine—e g , complicated by paraplegia

5 Tumours of the vertebræ

6 Post operative nursing of cases of spinal fusion

7 Transport of medical and surgical cases requiring immobilisation in recumbency

ANTERIOR SHELLS

1 *In the intermediate stage of treatment of tuberculous* spines in children after hyperextension on Bradford frames, to allow collapse of vertebræ and development of compensatory curves

2 *For cases of paraplegia*

3 Post-operative treatment of laminectomy

4 For the nursing of incontinent cases, such as spina bifida when the cast may be waterproofed with varnish or Pexuloid

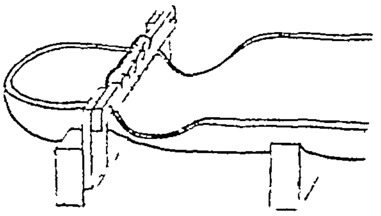

FIG 8.—The restrainer attached to a plaster bed

CONCLUSION

Plaster beds and shells made by this method have the following practical advantages (1) they are made in 10–15 mins , (2) they dispense with the need for preparing many plaster bandages (3) they are of even texture and good finish (4) they are light—a bed for an average adult weighs 5½ lb , unmounted , (5) the mounting facilitates nursing and transport, and with the accurate moulding obtained the adult patient needs to be turned only once a month and pressure sores occur very rarely (7) they are durable—a bed generally lasts twelve months.

Our thanks are due to the medical committee of the Royal National Orthopædic Hospital for permission to publish this account to Miss Williams matron at Stanmore for many helpful suggestions; to Dr C W Durward, for his pains with the photography; and especially to Mr H. J Seddon for his excellent teaching and his invaluable aid in the production of this paper

RAPID AMBULATORY TREATMENT OF SCABIES WITH A BENZYL BENZOATE LOTION

By A Kissmeyer, M.D

PHYSICIAN IN CHARGE OF THE SKIN DEPARTMENT
KOMMUNEHOSPITAL, COPENHAGEN

It is very important that the treatment of a disease such as scabies in the first place should be ambulatory and inexpensive and secondly it should not irritate the often already scratched skin of the patient It seems usual in France and America to regard scabies as a disease necessitating a stay in hospital, if one can judge from the descriptions given in dermatological journals MacKenna (1933) appears to calculate that 5–8 days are required for a cure and he regards treatment by Mitigal as being the simplest and states that it will cure an average case of scabies in 10 days Roxburgh (1936) recommends the treatment of scabies by Kathiolan which is said to produce a cure in 24 hours or by sulphur ointment which takes three days

In the skin department of the Kommunehospital we *treat between 2000 and 2500 cases* of scabies in a year by a method that can be carried out in one hour Formerly we used the kathiolan of Ehlers Marcussen a method of treatment which saved the patient many days stay in hospital and gave very good results This treatment however as with all sulphur remedies often caused an extremely disagreeable sulphur dermatitis In 1932 therefore I introduced treatment by benzyl benzoate It was first tried some 25 years ago by Ludvig Nielsen with great success With the help of the hospital dispenser we improved the formula of the benzyl benzoate lotion and simplified the method of treatment so that it could be carried out in 45 minutes without causing any damage to the skin Since January 1933 we have not used any other method and we have treated some 8000 cases of scabies in which it has proved practically ideal

The whole treatment takes less than one hour and is an ambulatory one only children of under one year having to be treated in hospital It very seldom gives rise to any dermatitis or irritation of the skin and even cases of scabies pyogenically infected, and very young children can be treated without any serious after-effects It is an inexpensive treatment costing about 6d per head for the clinic patient and 2s per head for private patients

METHOD

The formula consists of equal parts of :—

Soft soap (B P 1932)
Isopropyl alcohol
(CH) CHOH
Benzyl benzoate
C H COOCH C H

The quantity necessary for each patient is about 150 grammes The patient anoints the whole body with soft soap rubbed with special care into those parts commonly attacked by the acarus He then soaks in a warm bath at 100 F for 10 mins rubbing himself during the bath While wet the body is brushed all over with the lotion for 5 mins using a brush of Russian pig bristle special attention being paid to the affected parts The patient then rests allowing the body to dry and then continues the brushing for a further 5 mins after which the body is gently dried with a towel and the patient resumes the clothes worn before the treatment was started. Twenty four hours later a second bath is taken and clean clothes put on Underclothes are not disinfected but only washed and if possible boiled Bedclothes should be boiled or otherwise sterilised It is very important that all members of a family or household should be treated on the same day even though they may not show any signs of scabies

We have treated some 8000 cases of scabies in this way and it has proved to be an ideal, effective and cheap method giving rise to no serious post therapeutic dermatitis

MENTAL CHANGES IN FAMILIES AFFECTED BY DYSTROPHIA MYOTONICA

By Otto Maas, M.D

AND

A S Paterson, M.A Oxon M.D
F R C P Edin M R C.P Lond

(*From the National Hospital Queen square London*)

This paper is a preliminary report of an investigation into the mental symptoms occurring in patients with definite signs of dystrophia myotonica and in members of their families. Chiefly through the courtesy of the honorary physicians to the National Hospital Queen square, and particularly Dr F Arnold Carmichael, Director of Research we have been able to examine 20 such persons On the result of the neurological examination (O M) they were divided into three groups: (1) those who were seriously affected by the disease to the extent of being incapacitated either by paralysis or by cataract; (2) those who showed definite signs of the disease such as wasting of the hand muscles together with the characteristic myotonic reaction in these muscles and (3) relatives who were wholly or almost free from physical signs In each case as thorough a psychiatric examination as possible was made (A S P)

THE FINDINGS

Innate Intelligence of Patients—Of the 20 patients 4 adults were congenital mental defectives their mental ages being nine seven six and six In addition 7 had been backward at school they had not been sufficiently defective to be sent to a special school but were about two years behind other children The remaining 18 appeared to have school records that were average or above average

Intellectual Deterioration—An attempt was made to determine whether any patients normal at birth had later deteriorated intellectually because of the disease Of the 7 backward patients only 2 a woman aged sixty and a man aged fifty-six showed signs of much mental deterioration since school days this deterioration was mainly in their memory Of the 18 who at school had shown intelligence which was average or above average, 14 were over twenty, and 7 of these showed distinct deterioration when tested for recent memory, capacity for doing simple calculations, immediate recall, and grasp of a simple story

Muscle Wasting in Relation to Mental Changes—In our first group which included all those with severe affection of the muscles, 3 were congenital mental defectives, 6 were backward at school, and 3 more although they had been normal at school, had later deteriorated in respect of memory, &c Thus among the 13 severely affected physically there was only 1 whose intellectual deterioration was doubtful, and the group included 3 patients, with hysteric, paranoid, and epileptoid symptoms Of the second group—those with slight muscular wasting—3 had deteriorated in intelligence, and 3 showed other mental changes (2 were chronically elated and 1 had schizoid symptoms) Thus 6 were affected mentally and 6 were unaffected Of the third group—those with no definite muscular changes—3 were affected as regards intelligence (1 was a congenital mental defective, 1 was backward, and 1 deteriorated in later life) The other 4 were unaffected mentally

It may be concluded then that mental changes are almost always present where there is much muscular wasting Where the muscular changes are less pronounced, there may or may not be pronounced mental change

Temperament—A characteristic temperament was apparent in nearly all the cases, whether there was mental deterioration or not The patients were persistently and almost morbidly cheerful, and usually somewhat condescending This state of mind was seen in cases with little or no intellectual change, and the trait was exaggerated in two of them into a state resembling chronic hypomania None of the patients examined were described by relatives as irritable or quick tempered, except 3 of the 4 mental defectives , and even they were on the whole quiet and well behaved

Reaction Types—Despite a certain similarity of temperament in all these patients, there were some whose symptoms recalled those of the classical reaction types

1 *Schizoid Type*—A man aged 22, with mild muscular changes Two years previously he had begun to lose interest in things and became seclusive He was conscious of muscular weakness, and he had been impotent since the age of 16 He was unemployable, for he was casual, slow, and inefficient There was no trend and no voices There was good rapport, and he was persistently cheerful and happy

2 *Paranoid Type*—Man aged 50, with gross muscle changes After 16 years of married life he left his wife in the belief that she was a prostitute, which was untrue He still tried to keep on friendly terms with his wife after taking up with another woman He was an able man and head clerk in an insurance company

3 *Epileptoid Type*—Man aged 54 with gross muscle changes After marriage at 28 he began to have atypical fits when his head would suddenly fall forward and he would remain motionless for a minute or two with his tongue out He had a cheerful disposition and was somewhat demented.

4 *Hypomanic Type*—There were two of these One was a woman of 65 who was severely affected in her muscles She had lost her sight in an accident when 22 She was persistently mildly elated and was called "Sunshine She always believed her sight would be restored She called the doctors "My Lords and said she would give them 20 guineas for some small errand.

5 *Hysteroid Type*—A man aged 35, showing severe muscle changes He was backward at school and later did odd jobs He was popular at spiritualistic séances where he "saw the words written up," and also "astral bodies" He thus enjoyed the limelight and his belief in his own supernatural powers

DISCUSSION

Poor intelligence has often been described in dystrophia myotonica (Adie and Greenfield 1923, Bramwell and Addis 1913, Curschmann 1925, Baake and Voss 1917, Naegeli 1917, Hauptmann 1919) Certain writers (e g , Hauptmann) have held that it is something accidental, and not germane to the disease, and it has been said that the intelligence is not much below what one would expect in the low social stratum to which the patients belong From our observations, however, it appears that where a patient has severe muscular wasting his mind is almost always affected also, which suggests that the mental changes are really part of the disease Where there is less muscular wasting it is less likely that the patient's mind will be affected As the present series included, for example, a chartered accountant and a scientific photographer among those with intellectual deterioration, this cannot be attributed to the disease occurring in people belonging to the lowest social stratum The persistent cheerfulness shown was all the more striking in view of the pitiable physical state and dreary surroundings in which most of them lived

Curschmann (1925) and others have said that serious mental disorder is not characteristic of the disease, and the only case we can find on record is that of Fischer (1920) Among our 29, however, there were 4 patients suffering from serious congenital mental defect, another was diagnosed in a mental hospital as a case of schizophrenia, and we considered that another 6 might have been brought to a physician for an opinion on their mental state As already stated, 6 patients had symptoms approximating to those of the classical reaction types , but the clinical picture was never quite typical—probably because the reaction to difficult circumstances was occurring in persons with a particular temperament

Dystrophia myotonica is undoubtedly a disease entity, dependent on a defect which is inherited, and degeneration of certain endocrine glands has been recorded It is therefore of particular interest to know whether the temperament found in the disease is at all constant, and whether those who show mental changes have any symptoms in common If this were so, it might be possible in time to correlate the mental with particular physical changes

SUMMARY

1 Twenty nine persons from families affected by dystrophia myotonica were subjected to psychiatric examination, and seventeen of them were found to be of low intelligence In eleven of these the intellectual defect was congenital, four adults being mental defectives with mental ages of 9, 7, 6, and 6, while seven had been backward at school. The remaining six had been normal at school but had since deteriorated

2 Where there is much muscular wasting, there are almost always mental changes Where muscular wasting is slight or absent there may or may not be gross mental changes

3 Six of the twenty nine presented clinical pictures in some respects resembling classical syndromes of mental disorder One was diagnosed in a mental

hospital as a case of schizophrenia one had delusions that his wife was immoral one had fits and became somewhat demented one was a hysteric and a spiritualistic medium and two were chronically elated

4 The series was not confined to those in the lowest stratum of the social scale but included several brain workers The intellectual enfeeblement was therefore not merely due to unfavourable environment in early life.

5 A definite temperament was found in so many cases as to seem characteristic of the disease. It consisted in persistent and almost morbid cheerfulness mild grandiosity and a lack of drive and initiative.

Permission to see cases has been granted us by the honorary physicians to the National Hospital, Queen square Mr Charles Goulden Mr T C Summers Dr Redvers Ironside and Group Captain H E Burton R.A.F *to whom we would like to express our thanks* One of us (O M) is indebted to the Medical Research Council for a grant which made this work possible The necessity for the investigation of mental changes became noticeable in the course of his studies in the heredity of the disease

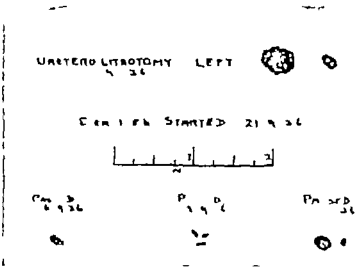
POSTURE AND DIURESIS IN THE TREATMENT OF RENAL CALCULI

By R Ogier Ward M.Ch Oxon F R C S Eng.
ASSISTANT SURGEON TO ST PETER'S HOSPITAL, LONDON

It is common practice to advise patients who suffer from renal calculi to drink large amounts of water partly in the hope that salts which might be deposited as crystals will thereby be held in solution, and partly to ensure the thorough washing out of the urinary tract. Such treatment may be used either to prevent the formation of renal calculi or after a stone has been removed by a surgical operation to prevent the formation of another It has been pointed out by Swift Joly that in the erect posture each lower renal calyx is undrained by gravity and although it is unlikely that in health absolute stasis ever exists from this cause yet it is a fact that renal calculi most commonly take origin in this site, and from small beginnings grow until they fill the lower calyx and then hook over the lower part of the kidney into the uretero pelvic juncture It seems clear that if this part of the urinary tract did not have to empty itself uphill renal calculi would not develop so commonly as the minute deposits of crystals from which they take origin would be washed out when they were still so small that they would readily pass down the ureter

The other position in the urinary tract where there is a particular tendency for stones to form is in the bladder behind the intravesical projection of an enlarged prostate. This area is also undrained by gravity and is very inefficiently cleared in the act of micturition because in such cases residual urine is commonly present

I first became interested in posture in relationship to the formation of renal calculi when in 1921 I had under my care a patient with enormous stones in each kidney He had suffered from gunshot wounds in the lower extremities for which he had been treated for many months by splints and extension *his feet being kept continuously higher than his head* It seemed clear that the stone formation in this case was the combined result of sepsis and renal stasis



Renal calculi removed by operation (above) and passed after exercises

METHOD

For a good many years I have been in the habit of encouraging patients upon whom I have operated for renal calculi to do more than merely maintain intense diuresis for I have given them exercises in posture to carry out combined with this The instructions are as follows One day out of each week *on waking drink one third of a litre bottle* of Evian, Contrexéville, Vichy Vittel or other water then adopt the following postures spending five minutes in each —

(1) Lying flat on the back with only one pillow under the head.

(2) Lying flat on the face

(3) Lying on the right side

(4) Lying on the left side

(5) Kneeling with the knees drawn up to make the thighs vertical whilst the trunk is bent downwards onto the bed, so that you are resting on the upper part of your chest, the head being turned to one side By this means the body is turned half upside-down.

After resting for five minutes drink the second third of the bottle and repeat the postures as before Then drink the remainder of the bottle, and after a short rest and a short walk take breakfast.

EFFECTS

In a recent case the benefits of such treatment were unusually obvious.

The patient a man aged 48 in the middle of August had suffered from an attack of severe left renal colic He had had no other symptoms of calculous disease nor had he ever had pain referred to the right side of his urinary tract Radiograms showed in the left uretero-pelvic juncture a single stone about 8 mm in diameter (see Figure) which was proved by a Uroselectan radiogram to be causing considerable hydronephrosis In the bottom of the lower calyx of the same kidney was a much smaller stone 3 mm in diameter *But it was found that both kidneys were affected with calculous disease for in the* lowest part of the lower calyx of the opposite kidney was one small stone and two others much more minute

On Sept. 1st the stones were removed from the left kidney by pyelolithotomy the larger one from the uretero-pelvic juncture the other by means of forceps dipped into the lower calyx. On Sept 21st the above mentioned exercises were begun and performed daily On the

26th, after an attack of renal colic, on the right side this time one small and very rough calculus was passed Further colic on the right side occurred on the 29th, followed by the passage of three small fragments of stone A radiogram on this date showed the largest calculus from the right kidney to be now held up in the ureter at the level of the right sacro iliac synchondrosis This and another piece were passed on Oct 2nd. A radiogram taken on Nov 30th shows the urinary tract to be now clear of calculi

The results obtained in this case demonstrated very clearly the value of this method of drainage of the kidneys by postures, and it seems reasonable to hope that this patient may, if he continues such treatment, avoid the formation of further stones The most important posture in my opinion is the knee chest position, which can only be improved upon by those patients who can stand on the head or upside down on the neck and shoulders

CLINICAL AND LABORATORY NOTES

DIFFUSE GASTRIC POLYPOSIS WITH PERFORATION OF THE DUODENUM

By C C Holman, M B Camb , F R C S Eng
SURGEON TO THE NORTHAMPTON GENERAL HOSPITAL

Diffuse gastric polyposis, to give it one of several names, is a rare disease In the case described below there was the very uncommon complication of acute perforation of the duodenum

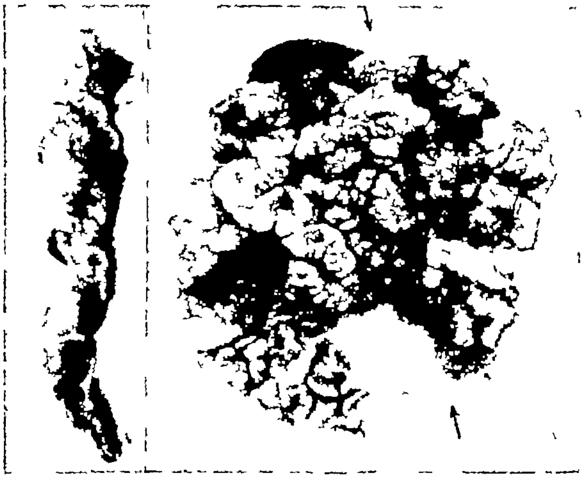


FIG 1 —The macroscopic appearance of the gastric mucosa with a section (left) through the part shown by the arrows

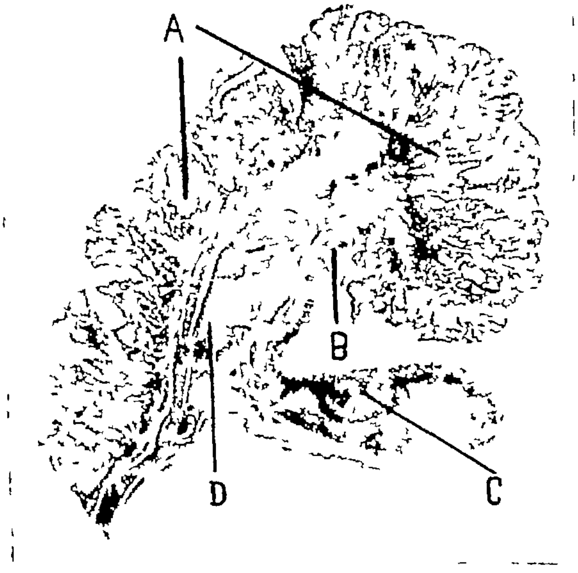

FIG 2.—Section of mucosa showing A œdematous polypoid mucosa changing abruptly at B to normal epithelium of the cardia (C) D muscle coat. (× 2½)

The patient, a married woman aged 45, of spare physique, was seen on August 13th, 1935, in consultation with Dr Morton Kahn For about a week she had been complaining of abdominal pain of a colicky nature, but previously her health had been good. At noon on August 13th she was seized with acute pain referred to the right side of the abdomen When I saw her she was in great pain the abdomen was rigid, but an indefinite tumour could be felt to the left of the umbilicus She was moved to the Northampton General Hospital and while there complained of the pain coming on in spasms Although her condition was suggestive of an acute perforation I was puzzled to account for the tumour Operation was clearly necessary and was carried out at 6 P M On opening the abdomen some extravasation was seen below the liver and a small perforation on the anterior wall of the first part of the duodenum was found and sutured I then examined the stomach which felt as though filled with some pultaceous material To ascertain what was wrong I opened the stomach and a polypoid condition of the mucosa was at once apparent I closed the incision and proceeded to remove about three-quarters of the stomach, dividing the duodenum at the level of the perforation and the stomach just proximal to the affected portion

Pathological report —Approximately three quarters of the pyloric end of the stomach, opened along the greater curve Apart from a narrow margin of normal gastric mucosa at the cut edge of the stomach, the whole area is thrown into irregular œdematous polypoid folds up to

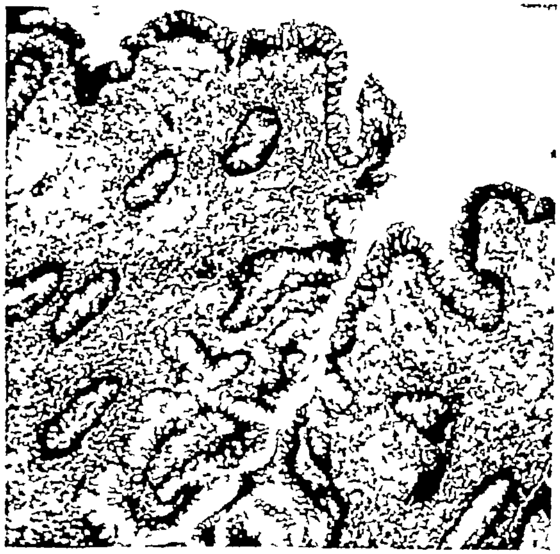

FIG 3.—Section of the mucosa showing œdema and chronic inflammation of the stroma (low magnification)

1 in thick. The condition ends abruptly at the pylorus but the duodenal mucous membrane appears inflamed and congested.

Sections show great thickening of the mucous membrane due largely to œdema and chronic inflammation of the stroma There is some evidence of proliferation of the glandular structures which consist of distended tubules lined by tall columnar mucous secreting cells There is a *sharp transition between the affected area and the normal* mucosa of the cardia.

Fortunately the patient made a good recovery and was seen in good health 15 months after leaving hospital.

The specimen is in the Museum of the Royal College of Surgeons and I am greatly indebted to the curator Dr L W Proger for sending me the photographs and the report

TROPICAL CHEIROPOMPHOLYX

By Denis J G Fitz Patrick L M

Tropical cheiropompholyx is endemic in tropical Africa and probably India Nothing is definitely known of its cause but presumptive evidence points to an anaerobic bacterium which attacks the palmar and interdigital aspect of the hands and the plantar aspect of the feet The condition is sometimes acute in those who wear gloves and footgear

The disease makes its appearance on the hands in the form of vesicles buried in the skin Irritation and destruction of the epidermis follow with serous discharge after which the eruption may (1) fade away usually to reappear again (2) cause rawness of the hand or (3) make its appearance on the feet causing lameness and great discomfort The only cases in my experience in which it has healed of its own accord are those in which the sufferers have moved to a more temperate clime After many failures and temporary successes however I found the following a specific coal tar 3 powdered coal 1 zinc oxide 4 lanolin and vaseline 12 This ointment is rubbed well into the affected parts, and no occlusive dressings are used apart from a loose glove or sock to prevent soiling of bedlinen In conjunction with the above resorcin soap was used Every case of tropical cheiropompholyx I have treated yielded within ten days and I have successfully employed the same treatment for squamous eczema For the moist types of eczema I use this powder zinc oxide 5 powdered talc 20

Lourenco Marques Portuguese East Africa.

MEDICAL SOCIETIES

BRITISH PSYCHOLOGICAL SOCIETY

At a joint meeting of this society (medical section) with the Institute for the Scientific Treatment of Delinquency on Dec 10th, 1936 Dr Edward Glover chairman of the scientific advisory committee of the Institute being in the chair a discussion on

The Unwilling Patient

was opened by Dr Denis Carroll, director of the Institute He discussed the technical problems arising when a patient who did not wish to be treated was coerced into attending a psychiatrist for the purpose of carrying out a course of treatment He deliberately excluded from discussion the very large numbers of *patients in whom the psycho-analyst* recognised unconscious unwillingness The patient treated under duress might be a delinquent for instance a man bound over with treatment as a condition a man who regarded treatment as punishment or as a means of evading punishment or a prisoner who agrees to be treated as a matter of discipline; or among non-delinquents might be instanced certain alcoholics psychotics under certificate neurotics and character cases manœuvred into treatment by relatives or friends and many children He confined his paper to the delinquent in whom he demonstrated that the lack of desire to get well is of the same nature as that found in non delinquent patients and consequently the technical problem reduced itself to that of adapting ordinary psychotherapeutic methods to the particular case of delinquents in such a way as to establish a positive drive to treatment

The special points were first that the lack of desire to get well was often quite conscious or only thinly disguised second the identification of the doctor with a harsh super ego was greatly facilitated by the nature of the situation This might be got over by making a strong positive contact at the first interview and/or by careful choice of the therapist Other devices were to diagnose the sign and quantity of the initial transference manifestations and so make it possible to plan how to be a good object in the Klein sense—e g by *arranging to appear* to the patient as a rescuer from his trouble Or the delinquency might be treated under the guise of treating some other condition—e.g a man repeatedly convicted of theft who was ostensibly treated for his lack of self-confidence without any apparent connexion between the doctor and the court Aggressive impulses and unconscious paranoid anxiety systems played a large part in the psychogenesis of delinquency as in psychosis the difference being that the psychotic dealt with these problems by flight from reality whereas the delinquent did so by manipulating reality by his delinquency He showed how this led to a difficulty in treating delinquents which was not present in psychotics The types of treatment possible were sociological physical and psychological In the first two of these the difficulty was administrative only in psychological treatment suggestion and superficial analysis could be facilitated for unwilling patients by deliberately coaxing a positive transference Such devices precluded deep analysis in which the underlying aggressive and paranoid systems had to be resolved It meant a long analysis with a long early negative stage and called for special qualities in the physician such as deep personal analysis great patience and the rare ability not to dislike such patients

Aim in treatment was important Radical cure could only be reached by deep analysis and resolution of negative transference; partial cure by stabilisation by sociological methods and suggestion The latter tended to produce greater inhibition than was present at the outset and was probably one of the ways in which moral method worked In some cases one might aim at alteration transmuting the delinquency by partial analysis into an obsessional state In methods aiming at partial cure duress did not necessarily prejudice the prognosis None of the methods were of avail if the physician allowed himself to be identified with the bad restraining parent Deep analysis was lengthy, and this fact had to be borne in mind in making the initial recommendation to the court It seemed that psychopathic personalities would *not* stabilise better by non-analytical methods though apparent cures would be easier Delinquency with neurosis would be easier to stabilise by non analytical methods than delinquency by itself

The criteria for deciding on psychotherapy rather than on other methods of treatment for the unwilling delinquent were, Dr Carroll considered, (1) Age, youth being best, a positive transference had to be present or the means to get it readily available (2) If a grip were needed, it should be adequate (3) Last and most important, the possibility of an unconscious drive being found which would induce willingness—e g , as would be evidenced by a desire for love or by a tendency to use the doctor as a whipping block or as a bolster between say the patient and his relatives Coercion was, he thought, sometimes desirable Some patients were too slippery unless forced , in others strong and rapid transference manifestations, apart from a transference neurosis, might make it desirable It might also be of service if the patient's rôle were complementary to the doctor's—e g , the presence of a gentle manner in the physician with a timid or effeminate patient A patient with difficulty in expressing or admitting to himself his angry, persecutory, or jealous reactions to real situations might respond well to force Coercion might provide an outlet for a masochistic type

Our knowledge of the treatment of delinquency was, concluded Dr Carroll, incomplete and he hoped research would be carried out on non recidivist criminals and into clinical types He did not think treatment need be more difficult in jail provided the doctor had a free hand without restrictions on secrecy and was able to continue treatment after discharge and provided also that treatment was voluntary and was not identified with punishment or its evasion He thought compulsion should be more deliberately used or avoided for those on probation than was the present fashion

TWO TYPES OF UNWILLINGNESS

Dr W H de B Hubert described the initial overwillingness of the delinquent patient who preferred probation, with treatment as a condition, to prison or who considered that while serving a sentence he might derive from treatment special consideration from authority or feel relieved of his sense of guilt at being punished by society because he believed that treatment implied that he was ill When the disadvantages of treatment had been encountered he would tend once more to show "unwillingness" towards his physician as he had shown by his previous behaviour his "unwillingness" towards society The unwillingness of the patient to be treated for functional nervous disorder apart from delinquency was not so much an attitude towards the physician as a member of society but was often an illogical reaction forming part of the total reactive pattern which made up the patient's illness The speaker took as examples of these two types of unwillingness the homosexual and the schizophrenic patient

In discussing the view that there was a congenital and absolute tendency towards homosexuality in at least a portion of that type of patient Dr Hubert said that isolation from the opposite sex showed the large part played by circumstance in the development of homosexuality , but, from careful observation of a large number of cases, several authorities had agreed upon an irresistible congenital determinant towards it , more recent authorities, starting with Freud, introduced the psycho dynamic point of view , while admitting a congenital factor varying in different cases they found evidence also of such a tendency in everyone and demonstrated particular psychological mechanisms in early life which allowed the tendency to operate Unwillingness in patients of this class therefore might not only be a very cogent argument but also, in a totalistic sense, a deep seated biological unwillingness

In society the powerful factor set against homosexuality, against which the patient showed his unwillingness, consisted of two parts the religious and moral aspect and the concept of anti social behaviour defined in a particular legal code These were sometimes erroneously assumed to be the same Homosexuality appeared first in legal code in Roman law of the fourth century when the penalty of vindices flammæ was fixed Modern criminological views were derived with modifications from that, but a turning point in attitude occurred in France at the time of the revolution The nations might now be divided into two groups, in one, which included England and the United States, homosexuality was condemned in toto , in the other, which included France, Belgium, Italy, and Japan, homosexuality was not punished except in special circumstances The variation in legal code appeared to have little influence on the prevalence of the condition These various factors provided the patient with a classical tradition which gave him justification for his attitude In dealing practically with a case one had difficulty in knowing at what result one was aiming and one might regard the patient's unwillingness as the point at which one could see in condensation a historically developed behaviour anomaly up against its logical counterpart The differences in social relation and in attitude towards treatment in the female homosexual was also discussed

Homosexuality had to be viewed as a behaviour reaction resulting, first, from a biological anomaly , secondly, a complex personal development , thirdly, the peculiar position society had evolved as his environment While it was too early to speak definitely, evidence was collecting which would probably allow the definition of various classes of homosexuals on the basis of their types of total behaviour anomaly, of which overt homosexuality was but a part Then the factor of unwillingness would be much more clearly defined One might then hope to see clearly (1) in what cases no psychological modification could be hoped for, (2) when the general behaviour reaction could be altered by therapy to help the individual in his relationship to society, and (3) in what cases a heterosexual development might be attained

In his other example of an unwilling patient Dr Hubert described the change in imagery and thought process in terms of function analysis which he had observed in a case of schizophrenia occurring at the same time as a change from a willing to an unwilling attitude, which seemed to indicate the mechanism by which such an alteration could occur in a large group of patients suffering from this disorder

DISCUSSION

Dr O H Woodcock said that though there were drawbacks to classification he thought that among unwilling patients some groups stood out. There were the sullen silent type and the garrulous who kept up a constant flow of talk away from the point Then there were the persistently innocent who maintained that there was mistaken identity and the really sensitive with a pronounced feeling of inferiority; one of that kind had ceased to attend because she felt the doctor must be bored with her Absenteeism was a common form of resistance The delinquent s life was often so hard that he responded readily to the doctor s attitude

Dr J R **Rees** thought that inexperience on the part of the psychotherapeutist was one cause of the patient s unwillingness to start treatment. Most patients became willing after a few attendances The non judicial and non moral attitude of the doctor changed that of the patient surprisingly The speaker had found that his opening gambit a statement that he had no connexion with the court and was only interested in the individual, was often successful He separated the delinquent s action from his self and asked the patient to coöperate with him in finding out why the symptom appeared The homosexuals formed a group by themselves they had usually read books on the subject which left them hopeless; treatment was consequently best directed to the other symptoms which were always present. He thought the results of treatment of those serving sentences disappointing but he was encouraged by the numbers coming for treatment of their own accord before getting into the hands of the police they were very willing patients He thought it very important that every case should be seen between their hearing and the passing of sentence; coöperation was then much easier and the doctor could give a much more hopeful prognosis to the court

Dr **Glover** said that special methods of approach might be necessary in dealing with delinquents but the methods of treatment themselves were not new except in the way they were combined

Dr **Prynns Hopkins** agreed with Dr Rees that the time at which a delinquent was brought for treatment was extremely important. He mentioned some observations of electrogalvanic response in genuine murderers in Moscow These had shown that the greatest emotions were aroused immediately after arrest; apparently at that stage conflict was aroused partly by apprehension for the future and partly by the conflict between the super-ego and the action After trial judgment and serving term the conflicts were quieted down This work was of importance in showing when would be the best time to treat delinquents

Dr H G **Baynes** said that nearly everyone who had committed an anti-social act expected punishment. He thought direct transference was necessary in treatment and that transference achieved in a roundabout fashion was on the wrong basis

Dr E A **Bennet** thought the objective method of approach was often best as some patients preferred not to be fully understood at first In America automatic writing and drawing had been used for patients that were unapproachable He had found that automatic writing could be produced by quite simple devices and was a successful initial method more especially for schizophrenic patients

Dr J D W **Pearce** said that most of his juvenile court cases had been seen before judgment had been given and he would be interested to find out if such children responded better than the rest to treatment

Dr W R. **Bion** considered that collusion with the relatives put the analyst in an awkward position which forced him to take up a false attitude

Dr **Paterson Brown** had found that in child guidance clinics the analyst had to reach the layer of depression and then he could turn an unwilling into a willing patient

Dr **John Rickman** thought it important that the patient should be assured that he would be given treatment after discharge from prison

Dr **Glover** suggested that the investigation of empirical methods was of importance in a new science

REPLY

Dr **Hubert** agreed with Dr Rickman that the continuation of treatment after discharge from prison was essential That time was particularly difficult for the patient —Dr **Carroll** expressed disappointment that his provocative points had not been challenged. He agreed with other speakers that treatment should continue under the same physician after the patient s discharge from prison

MANCHESTER MEDICAL SOCIETY

At a meeting of this society on Dec 2nd 1936 Dr R E **Lane** opened a discussion on

Industrial Diseases

limiting his survey to industrial poisons There was he said a great difference between the toxicity of a substance per se and the extent to which it constituted a health hazard in industry Toxicity was dependent on chemical nature the danger to health on the physical properties of the compounds handled The ease of absorption was a vital point In the motor body building industry lead poisoning arose as a result of the inhalation of fine particles of metallic lead An attack of metal fume fever was brought on only by the inhalation of metal fume in a very fine state of subdivision and dispersion If the same fume were allowed to stand for a short time before inhalation fever no longer occurred because a clumping of the particles had taken place; the chemical nature of the fume had not altered The clinical picture of industrial poisoning was often not what would be expected after reference to standard works on toxicology Arsenic was cited as an example Dr Lane went on to illustrate from the lead trades the type of prophylactic measures to be adopted in any dangerous trade; the collaboration between medical and other technical experts; the doctor s preparedness with accurate knowledge when consulted by the employer

Dr W M **Goldblatt** referred to the prevalent lack of knowledge of the effects of industrial products on the worker Often attention was only drawn to the dangers after calamities had occurred Systematic research was needed in industrial medicine At any moment a worker might present some obscure and unsuspected idiosyncrasy when the known facts about a product had led to a belief in its harmlessness Criteria should be worked out for the detection of susceptible subjects particularly to skin hazards and such workers allocated to employment remote from exposure A grave responsibility rested on the practitioner who diagnosed industrial disease He should not conclude that a man was suffering from an industrial disease just because he presented a symptom of a condition which might arise from his work It was unwise for the dermatologist to conclude that a skin irritation was due to a dyed garment because on previous occasions he had come across cases attributed to this dye The same name often referred to dyes of different composition. There were, however, difficulties in carrying out investigations which must not interfere with production on the one hand or on the other with the morale of workmen a little suspicious of medical service in industry Routine blood urine, and X ray examinations could only be made with careful organisation and administration

Dr J M Davidson spoke of the importance of obtaining a full employment history and the significance of trifling symptoms New risks arose from new uses of old poisons and new industrial processes, as in the risk from electric arc welding and manganese poisoning

Mr Harri Heap referred to the importance of accurate methods of chemical analysis which had thrown new light on lead poisoning There was, he said, a close relationship between lead and calcium metabolism in the body and need for making sure of the normal occurrence in the body of various mineral elements

REVIEWS AND NOTICES OF BOOKS

Paget's Disease of the Nipple

By Keith Inglis, M D, Ch M, Professor of Pathology in the University of Sydney London Humphrey Milford, Oxford University Press 1936 Pp 233 36*s*

This monograph is the product of a great deal of painstaking histological research, carried out with one eye on the clinical appearances of Paget's disease and the skin lesions which resemble it so closely It is illustrated by numerous beautifully reproduced microphotographs, and since it contains a full bibliography, with brief but pertinent criticisms of many of the articles, the book can fairly claim to be the most complete treatise on Paget's disease which has so far appeared in English

Detailed descriptions are given of 8 cases in which Paget's disease of the epidermis and ducts was present without scirrhous carcinoma in the breast, of a further 7 cases in which scirrhous carcinoma also was found infiltrating the connective tissue of the breast, and of a third group of 8 cases in which it was doubtful whether the cancerous process of Paget's disease had or had not given rise to scirrhous carcinoma of the breast Prof Inglis's work confirms the observations already made by Muir and Cheatle, and it leads him to conclude that in Paget's disease the epithelium lining the ducts is invaded by cancer cells which spread within it both outwards to the skin and downwards into the ducts from a primary focus close to the duct outlet

Subsequent chapters describe cancerous infiltration of the nipple by cancer spreading from the breast, simple eczema of the nipple, cancer en cuirasse, and certain primary growths of the nipple, all of which have to be differentiated from Paget's disease Several chapters are devoted to precancerous changes in squamous epithelium in many parts of the body, including extra mammary Paget's disease, and the author describes how they may be distinguished from true Paget's disease of the nipple Some of this section is not easy to follow but the chief feature upon which the author lays stress is that whereas Paget's disease is characterised by invasion of healthy epithelium by cancer cells in these other conditions the cells of the epithelium are themselves altered by degenerative hyperplastic, and neoplastic disease

Though there are slight differences between the views held by Inglis and those previously expressed by Muir the essential fact upon which both are agreed is that Paget's disease of the nipple indicates widely spreading cancer in the ducts of the breast which demands equally extensive treatment No one, however, has yet stated clearly the exact relationship between the Paget cells in the ducts and the cells of the scirrhous carcinoma which forms eventually in the breast substance

Williams' Obstetrics

Seventh edition By Henricus J Stander, M D, F A C S, Professor of Obstetrics and Gynecology, Cornell University Medical College, Obstetrician and Gynecologist-in-Chief, New York Hospital, and Director of the Lying in Hospital, New York City London D Appleton Century Co Inc 1936 Pp 1269 40*s*

Whitridge Williams died in 1931, one year after he had revised the sixth edition of his text book of obstetrics The present issue has been completely revised, retaining as much as possible of Dr Williams's text as is consistent with new developments in obstetrics, the general plan of the book remaining unchanged Three new chapters have been added, one dealing with the hormones as related to pregnancy, another with urinary complications particularly pyelitis, and a third with analgesia and anæsthesia The book is stated to embody the principles of obstetrics as carried out at the Johns Hopkins Hospital, and as such remains predominantly conservative in its teachings The physiology of childbirth occupies more than a third of the book, this section is of great interest and abundantly illustrated

As one of the most popular and widely read works on obstetrics in America it would be of interest to compare the principles enunciated in this book with current teaching in this country Take the chapter dealing with the treatment of antepartum hæmorrhage There are few who do not teach that the vaginal pack is virtually useless as a hæmostatic, particularly in the hands of the doctor faced with such an emergency, perhaps single handed, in the patient's home Yet English text books lack the courage to condemn this treatment in print In this book the "general practitioner is strongly warned against the employment of the vaginal pack " Or take the vexed question of the management of a case with a minor degree of disproportion—"We believe that the claims of the advocates of the induction of premature labor may be disposed of by a reductio ad absurdum—namely that better fetal results could be obtained by allowing all patients in whom it appears indicated to go to full term and performing craniotomy whenever spontaneous labor does not occur " But it would be easy to give equally telling extracts from any chapter of the book, more especially perhaps that on amnesia, analgesia, and anæsthesia

The work is well produced paper and type are good the illustrations are excellent and *numerous* and as is usual in American text-books there is an extensive bibliography at the end of each chapter Those who teach and practise obstetrics will find the matter and advice contained in this volume eminently practical and sound and students may be assured that there is little which would not be accepted at obstetric examinations in this country

---

Food and the Principles of Dietetics

Eighth edition By ROBERT HUTCHISON M.D LL.D F R C P Consulting Physician to the London Hospital and to the Hospital for Sick Children Great Ormond street and V H MOTTRAM M A Professor of Physiology at King s College of Household and Social Science University *of London, London Edward Arnold and Co* 1036 Pp 634 21s

THIS new edition the preface states has been necessary after a lapse of only three years because of the pace now set by research in nutrition For the most part indeed the alterations and additions are made on account of recent research. Chemical formulæ now take their place in the descriptions of vitamins B_1 and C and the separate factors of vitamin B_2 are mentioned Dr Corry Mann s experiment which proved the great advantage of giving extra milk to school boys is described and McCance and Shipp s analyses have caused profound modification of the chapters on fish and meat The account of the changes induced by cooking no longer speaks of pellicle formation It must be a matter of regret to the authors that the analyses of fruit, vegetable and nuts by McCance Widdowson and Shackleton were published too late to be utilised in this edition. The book has also been revised in other respects ; a charming and characteristic chapter on the history of dietetics has been inserted at the beginning from which one gathers that Hippocrates s *remarks on digestibility were as penetrating as any* recorded before the coming of chemistry in the nineteenth century Diets are suggested for expectant and lactating mothers and for those in training for athletics The basal requirements in calories computed by the B M A the Ministry of Health and the League s technical committee are set out

Originally based on lectures given to students at the London Hospital in 1000 and in spite of all the growth and change it has suffered in the intervening period this book still retains the simple wording and freshness of interest of a great teacher It covers a very wide field starting with an account of the constituents of food and their energy equivalents, going on to consider food requirements in *various circumstances* and then giving a detailed account of almost every conceivable article of food and drink The origin structure, nutritive value digestibility cost methods of cooking and uses in dietetics are gone into for nearly every item While the book is suitable for any layman who wishes to learn about food and for *dietitians it was presumably written primarily for* doctors They might like still more information for instance about the relation of vitamin D to the male sex hormone and œstrin about the use of high carbohydrate diets in diabetes and about canning

Many groups of readers will be grateful to the authors for presenting so much useful information *in such an acceptable manner The book is full* of common sense and understanding and in spite of the necessary amount of detail it is easy to read

Employment and the Depressed Areas

By H POWYS GREENWOOD London George Routledge and Sons Ltd 1036 Pp 167 3s 6d

MEDICAL men and women are citizens and the subject discussed here is of urgent importance to all concerned for the welfare of their country The economic body of the country *is grievously sick in* some of its members the sickness has persisted unduly long and it might almost seem that the prospect of the special areas is one of lingering death Mr Greenwood s interest has been stirred primarily by a visit to West Cumberland the least known and realised of the special areas He might well be *downcast after seeing Arlecdon* but he refuses to regard the position there or elsewhere as hopeless And with refreshing optimism he writes of areas of opportunity and entitles his book Employment.

There are early chapters on the history of unemployment on economic and political theory and on the totalitarian states which provide interesting reading These lead to the main thesis which develops *not* only the necessity but also the feasibility of attracting new industries into the areas Everyone recognises that the old-established industries will never recover their former prosperity The social services which have been introduced are admirably served by devoted workers but these are palliatives salves to a wound means of easing the pain of unemployment There must be new remedies and a break with tradition if recovery is to take place Mr Greenwood is convinced that this break lies in the redirection of industry by inducements to settle in the areas and the recognition by industrialists that *there is a profit*able field of opportunity This thesis gains *support* from the views expressed by the late Commissioner for the Special Areas in a report which is reviewed on another page Mr Malcolm Stewart recommends the control of further expansion of industry in Greater London and the offer by the State of inducements *to attract industries to the special areas*

A Handbook of Hygiene for Students and Teachers

By CYRIL C EASTWOOD B Sc M.B M R C S L R C I D P H Assistant M O H Borough of Worthing formerly Lecturer in Hygiene and Physiology to the University of Leeds London : Edward Arnold and Co 1030 Pp 358 6s

THIS little book simple in diction and illustration really attains the high aim of teaching health *for it is free from banality and pedantry Some manuals* give the impression that the author is talking down to the reader ; but Dr Eastwood speaks to and not at his readers instilling confidence which is the beginning of understanding The book includes no more than every person should know of the working of his own body and of hygiene except perhaps some *aspects of school medicine with which teachers should* be familiar but which need not be taught specifically to their scholars. Dr Eastwood does not avoid technical words but he seldom uses them where he can replace them by words in the common vocabulary The few references to pathological conditions are introduced without mystery or alarm and mainly as *natural sequences to the neglect of hygiene*

Did we not know it from other sources this book would tell us that Dr Eastwood is an experienced teacher of physiology to the uninitiated, for he answers in anticipation the questions the novice is likely to ask and as he goes along he is careful to make sure that all is really understood He has produced an excellent book, of which we hope the circulation will accord with its merit When a new edition is called for, we would ask the author to reconsider "a naturally insensitive bowel" as one of the causes of constipation The chapter on reproduction might be enlarged, for its shortness suggests that the subject is being got out of the way In the chapter on foods the weights perhaps should be given in ounces as well as in grammes, and some indication added of the requirements of the body in terms of pounds and ounces of purchased foodstuffs

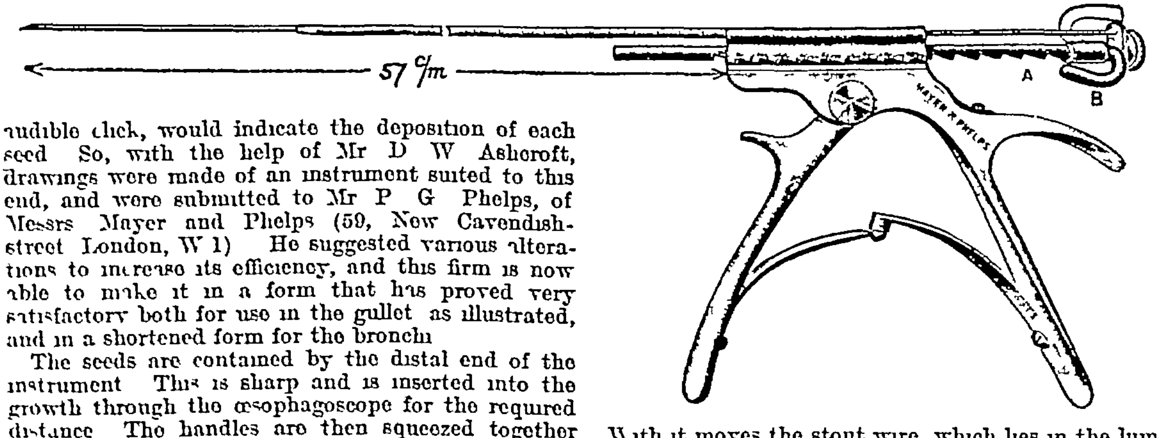
British Journal of Children's Diseases

In the October–December issue (vol xxxiii) Dr J S Cookson contributes a paper on the Erythrocyte Sedimentation-rate in Scarlet Fever and its Complications based on the study of 76 cases in various stages of the disease His conclusions are as follows (1) The sedimentation-rate (E S R) is a simple and sensitive method of determining the progress of the disease (2) A considerably raised E S R on the fourteenth day of disease means that complications either have developed or will develop (3) The E S R is useful in differentiating the type of albuminuria, a high rate indicating acute nephritis (4) With the exception of benign albuminuria and serum reactions the complications of scarlet fever produce a rise of E S.R before they cause signs and symptoms and during the presence of the complications (5) There is no definite relationship between the E S R and the other blood changes (6) The E S R is a useful index of the efficacy of treatment (7) It is altered by a change in plasma protein causing increased aggregation of red cells by alteration of the viscosity and indirectly related electric burdens —In an article on Streptococcal Peritonitis complicating Scarlet Fever Dr David Erskine, who records a personal case, states that peritonitis is a rare complication which may occur early, as in Rabinovitz's cases which were probably examples of a primary blood-borne infection of the peritoneum, or later when the peritonitis is probably due to inflammation of the mesenteric glands Erskine's case was that of a male infant aged 18 months, who developed peritonitis on the twenty-first day of a moderate attack of scarlet fever Laparotomy was performed the next day, when a large quantity of clear fluid without localisation or adhesions was found in the peritoneal cavity Cultures of the fluid showed a pure growth of hæmolytic streptococci Death took place 10 hours after the operation. The autopsy showed a fairly large indurated mass in the ileocæcal region containing several enlarged mesenteric glands, one of which had suppurated.—Dr L Helen Macfarlane records a case of Cancrum Oris following Measles The patient was a boy aged 3, in whom the complication developed on the eleventh day of a mild attack of measles Examination of the blood showed numerous white cells with 78 per cent polymorphonuclears, so that the condition was not one of agranulocytosis. Treatment by injections of antiscarlatinal serum, diphtheria antitoxin, and sulphostab was unsuccessful, and he died 5 days after the onset of cancrum oris Smears from the necrotic area in the mouth showed mixed Gram-positive and negative organisms but no spirilla The case was of special interest in that, unlike most victims of cancrum oris, the patient was a healthy, well-grown child until he contracted measles which appeared to be mild and uncomplicated by broncho-pneumonia or enteritis — In an article on the Treatment of Children by Artificial Light Dr Eva Morton states that she has obtained excellent results by ultra-violet ray radiation in cases of anæmia and debility, bronchitis and catarrhal conditions generally, and skin diseases of various kinds —The abstracts from current literature are devoted to urogenital diseases

NEW INVENTIONS

A NEW RADON-SEED INTRODUCER

In carrying out palliative treatment of carcinoma of the gullet by implantation of radon seeds I have never found an entirely satisfactory instrument It seemed desirable to have something which, by an audible click, would indicate the deposition of each seed So, with the help of Mr D W Ashcroft, drawings were made of an instrument suited to this end, and were submitted to Mr P G Phelps, of Messrs Mayer and Phelps (59, New Cavendish-street London, W 1) He suggested various alterations to increase its efficiency, and this firm is now able to make it in a form that has proved very satisfactory both for use in the gullet as illustrated, and in a shortened form for the bronchi



The seeds are contained by the distal end of the instrument This is sharp and is inserted into the growth through the œsophagoscope for the required distance The handles are then squeezed together and a single seed is deposited , this is indicated to the operator by a click By the use of the scale on the barrel (see Figure) each seed can be put exactly where the operator wishes until any desired grouping has been obtained

The instrument when fully charged contains ten "short Muir" seeds, each 7 mm long The method of loading is very simple and in brief depends on the turning of the ratchet "A" through a half circle by the lever "B" (see Figure) This disengages the ratchet and allows it to be drawn backward With it moves the stout wire, which lies in the lumen of the instrument and pushes out the seeds when the instrument is in action

F J CLEMINSON, F R C S,
Surgeon to the Ear and Throat Department of the Middlesex Hospital London

THE LANCET

LONDON: SATURDAY, JANUARY 2, 1937

MATHEMATICS AND MEDICINE

STATISTICS are curious things. They afford one of the few examples in which the use, or abuse, of mathematical methods tends to induce a strong emotional reaction in non-mathematical minds. This is because statisticians apply, to problems in which we are interested, a technique which we do not understand. It is exasperating, when we have studied a problem by methods that we have spent laborious years in mastering, to find our conclusions questioned, and perhaps refuted, by someone who could not have made the observations himself. It requires more equanimity than most of us possess to acknowledge that the fault is in ourselves. A colleague of a famous contemporary statesman has been quoted as complaining that he used figures as though they were adjectives. The medical profession as a whole would not find it easy to counter a similar charge. For most of us figures impinge on an educational blind spot. We have never been taught to recognise them for what they are. This is a misfortune, because simple statistical methods concern us far more closely than many of the things that we are forced to learn in the six long years of the medical curriculum. Many of our problems *are* statistical, and there is no other way of dealing with them. In preventive medicine this is so obvious that it has acquired general recognition. In laboratory work, though recognition has come more slowly, it is now widely realised that it is very unsafe to base conclusions on statistically inadequate data. In clinical medicine recognition is coming more slowly still—so slowly that many avoidable errors and a sad waste of material still hinder progress.

The kind of problem that demands statistical treatment is familiar to all of us. What is the therapeutic value of antipneumococcal or of anti-streptococcal serum? What is the expectation of life of patients who are operated on for carcinoma at various sites and in various stages of development? What are the relative merits of artificial pneumothorax or thoracoplasty in the treatment of phthisis? In all such problems, and they could be multiplied ad nauseam, the unknown or uncontrollable variables are so many that no sound conclusion can be based on the observation of a few cases or on the uncritical assessment of many. Clinical science, like any other, is essentially experimental. We do things to our patients and we see what happens. It has become a truism that the history of a science is the history of its technique, and the technique of seeing what happens when we attempt to control disease is as yet very poorly developed. Because it is poorly developed we still do many things that we ought not to do and leave undone much that ought to be done. The omission from the medical curriculum of a short course in statistical methods has led to an unfortunate misconception of the real difficulty that we have to face. It is sometimes supposed, by those who have conquered their repugnance to statisticians and all their works, that our technical problem can be solved by passing over our figures to a mathematical expert and letting him do his best, or worst, with them. That way there is no real salvation. The mathematical statistician is trained to deal with numerical observations as such. He can expose statistical fallacies, and by inquiry he can often get behind the face value of the figures and allow for factors that are not immediately obvious from the tabulated findings. But his ignorance of medicine makes it as difficult for him to appreciate all the possible sources of error as it is for the medical man who knows no statistics to assess the real significance of his figures. Much can of course be done by the method of liaison, especially when it is close and understanding, but to be fruitful, it demands some knowledge of statistical methods on the one hand, and some experience of medical problems on the other. In the form in which it is too commonly practised it has another fatal disadvantage. The statistician who is presented with a mass of figures from a long and laborious inquiry has not infrequently to report that they are of little or no value because they have been wrongly collected. The time to allow for statistical factors is when an inquiry is being planned, not when it is completed.

In this issue we commence the publication of a series of articles by Mr. A. BRADFORD HILL, D.Sc., of the London School of Hygiene, which will, we hope, be of service to those who desire to gain an insight into the application of simple statistical methods to problems of the kind that face them in their daily work. In his earlier articles Dr. HILL sets out, in simple terms and with a minimum of mathematics, the various methods that the statistician employs in assessing the significance of numerical results, illustrating each method by examples which will be of interest to the medical practitioner or medical officer of health. In his later articles he considers a number of common fallacies and difficulties of interpretation that arise in dealing with data of this kind. We believe that this clear exposition by a statistician who has had a wide experience of the problems with which medical men have to deal, and of the difficulties which post-graduate medical students encounter in grasping statistical principles, will be welcomed by many of our readers.

ORAL SEPSIS

WHEN OKELL and ELLIOTT[1] showed that a patient with pyorrhœa usually has organisms in his blood after tooth extractions—and sometimes even in the absence of any deliberate trauma—it was obvious that their findings might alter the outlook on oral sepsis. If it was easy for living organisms to reach the circulation from septic gums the time had come to think again about the importance of "closed" as contrasted with "open" sepsis. It is not surprising therefore to find Fish and Maclean[2] bringing forward observations and opinions which if correct will modify not only medical notions but also dental practice. In the first place they confirm Okell and Elliott's findings, and underline them by quoting the unpublished discovery by Round, Kirkpatrick, and Hails that bacteræmia may be produced in pyorrhœa patients by simply allowing them to chew hard sweets. From this they pass on to consider the working assumption that bacteria may live and multiply in the apices of living teeth, and that the absorption of these or their "toxins" may lead to local bony changes in the jaws and to diseases in remote parts of the body.

---

[1] Okell, C. C., and Elliott, S. D. (1935) *Lancet*, 2, 869.

Various careful observers have been able to grow streptococci from the pulp and apices of living teeth that have been extracted with special precautions against contamination from the gums, but it is questionable whether any hitherto available technique for this purpose has been really satisfactory. Fish and Maclean challenge both the technique and the positive findings. Setting on one side the well recognised pyogenic inflammations of the pulp and apices of dead teeth, they devote their attention to the common kind of case in which the teeth are alive but the maxillæ show bony modifications or other signs attributed to toxic absorption. Their conclusions may be summarised as follows. (1) At the apex of a tooth with living pulp there is never any histological sign of the round-celled infiltration that is the characteristic reaction of tissue to live streptococci, whereas when the pulp is dead, and streptococci are living in the necrotic material of the root canals, an intense round celled infiltration is always to be found. (2) All specimens of gum margin examined, even those from very young children, have shown some signs of round celled infiltration. It is well known that streptococci can nearly always be isolated with ease from the gums at all ages. (3) When teeth are extracted the organisms of the gums are pumped into the pulp by the rocking movements of the forceps, and that is why they can be found in sections of the extracted teeth (for the most part in the perivascular lymphatics). The same mechanism is held to account for the transient bacteræmia observed by Okell and Elliott, the organisms being pumped directly into the small blood-vessels. (4) With an appropriate technique, whereby the gum margins and pockets are partly sterilised and occluded by cautery, it is possible to extract teeth with living pulps from patients with pyorrhœa without contaminating either apex or pulp. The apices and pulps of such teeth, it is stated, were always sterile, whereas in controls where the gums were not cauterised they were always infected.

These interesting observations are rather unnecessarily overladed with arguments a priori. Not every pathologist will feel so certain as Fish and Maclean that the active infection of living tissues with *viridans* streptococci must inevitably be accompanied by a round celled reaction, or that streptococci must have a nidus of necrotic tissue if they are to maintain themselves for any time in the body. The "quiet periods" of relapsing staphylococcal osteomyelitis, for example, suggest other possibilities. But the clinical and pathological implications of the new work on oral sepsis are far reaching. Among them is the implication that the absorbing alveolar crests between pyorrhœic teeth, which are generally referred to as radiographically "infected," are in reality not infected at all, so that there is no reason why every mechanically useful live tooth should not be saved. The authors also say that the bacteræmia of extraction can be avoided as far as live teeth are concerned if the gums are prepared by preliminary cauterisation, and it is to be hoped that this statement, for which no direct evidence is produced, will be confirmed by actual experiment on an adequate scale. It is by no means apparent what effect the bacteræmia described by Okell and Elliott is likely to have upon the general health of otherwise normal persons, but there is one risk at least that might be eliminated by its prevention—namely, the determination of infective endocarditis in those with diseased or defective heart valves. And whatever the final verdict on these new observations, it is certainly a healthy sign that oral sepsis has come under serious experimental review.

FLUID AFTER OPERATION

Water has often been the therapeutic fashion. To-day, after a period when dehydration was hailed as the sovereign remedy, water is once more in the ascendant—or so it seems from a letter to an American contemporary which draws a touching picture of the earnest school mistress striving with daily drinking drills to make her charges water-conscious. In treatment the misuse of water is usually due to confusion of empiricism and reason. Fluid is useful in febrile perspiring patients, for instance, but the idea that it washes away bacterial toxins is ungrounded, and to try to flush out hypothetical and probably non-existent toxins from an eclamptic woman already sodden with unwanted fluid is neither logical nor desirable.

In many states of dehydration the need for water, or rather fluid, is obvious enough, and the patient in full possession of his faculties is not likely to suffer in silence. It is when he is no longer able to complain of thirst—or is forbidden to quench it—that the lack becomes a serious danger. This danger is fully recognised in the treatment of many conditions, such as diabetic coma, but we doubt whether the frequency and severity of postoperative dehydration is as widely realised as it should be. Many factors combine to deplete the fluid reserves of the patient who undergoes a major operation: preoperative starvation, hot operating theatres, excessive swaddling in blankets loss of blood, and postoperative vomiting may all take part and finally shock causes internal dislocations of fluid balance Elsewhere in our present issue Dr **Walther** reports some observations that illustrate both the gravity of surgical dehydration and the readiness with which it responds to treatment His data suggest that where the oral route is impassable saline is better given by rectum than intravenously and he surmises that fluid entering the circulation by way of the intestine may pick up protein in the liver and so become less liable to leak out of the vascular channel

---

[2] Fish, E. W., and Maclean, J. (1936) *Brit. dent. J.* 61, 336.

The present popularity of intravenous saline infusions gives these observations practical importance Not many years ago the surgeon would marshal an array of scalpels ligatures coils of rubber tubing and bottles of cocaine and would proceed to dissect out a vein tie in a cannula and squirt in saline with an inadequate rubber pistoned syringe Small wonder that the operation was reserved as a last desperate attempt to revive the moribund Nowadays the technique is so simple that there may be a real danger of causing harmful waterlogging of the lungs by over enthusiastic use of saline There are of course many surgical occasions when fluid cannot be given by mouth and a few when rectal administration is also impossible It is in these circumstances that Dr **Walther** regards plasma transfusion as the ideal But when fluid can be given by the alimentary tract it is clearly desirable to introduce it in this way which (unlike intravenous injection) at least allows the body to regulate the rate of absorption and to reject excess if necessary If further experience confirms Dr **Walther**'s conclusions they should prevent us from forgetting that the patient has a mouth and an alimentary tract designed for the absorption of fluid.

CONTROL OF VENEREAL DISEASES

Whether through ignorance or lack of interest the general public is usually apathetic to the control of venereal disease and this attitude is reflected in the tardiness with which public policy adapts itself to meet the changing needs of the problem In the United States where the incidence of venereal disease is high, the vigorous propaganda instituted by a zealous public health service has in recent years caused some stirring of the public conscience In 1935 the mayor of New York City appointed a commission representative of New York (City and State) to study the methods of control adopted in the Scandinavian countries and in Great Britain where it was thought that some measure of success had been achieved The report [1] of this commission, which is now available includes a review and appraisal of the administrative measures adopted in this country for the prevention diagnosis and treatment of venereal disease and a critical comparison of these methods with those adopted in the Scandinavian countries in the light of brief observation and available statistics

It seems that in Denmark Norway and Sweden as in some of the British Dominions venereal diseases are notifiable by law and treatment is compulsory If persuasive methods fail the health authorities have power to enforce submission to medical care, including admission to hospital if this is considered necessary—a precaution which is commonly employed in the early infectious stages Penalties may be inflicted on those who knowingly transmit infections and power is given to trace contacts and known sources of infection. Coercive measures may be adopted for the non-coöperative or defaulting patient The Scandinavian peoples are well accustomed to the discipline of social control so that it is possible to enforce these regulations without serious difficulty Frequent use of in patient facilities is necessary because the populations are scattered and the facilities of treatment are often inaccessible In highly industrialised Britain where the population is largely grouped in relatively small areas and traditionally resentful of interference with personal liberty, central facilities for treatment are readily accessible and regulation for compulsory treatment would be difficult to enforce In other respects the measures adopted in these countries are similar to our own and include free diagnosis and treatment for all regardless of economic status In comparing the results attributable to these schemes the commission finds that there has been no decline in the incidence of gonorrhœa in any of the countries and that in Great Britain it has possibly increased in prevalence On the other hand the figures indicate a general diminution in early syphilis the reported cases in 1933 showing an incidence of 7 per 100 000 in Sweden 20 in Denmark and 30 in Oslo the chief city of Norway The commission formed the opinion that in Sweden and Denmark at all events the reporting of cases was faithfully carried out by medical practitioners and that these figures fairly represent actual prevalence For this country the figures are less impressive , in 1933 the number of new cases of syphilis applying to treatment centres amounted to 21 525 an incidence of 56 per 100 000 in a population of 38 000 000 Clearly this figure is not the total incidence because no account is taken of patients treated elsewhere than at treatment centres In its report the commission makes the guarded suggestion that lack of legal power for the enforcement of treatment in this country may be partly responsible for the disparity while recognising that this absence of legislation is due to the peculiar nature of the local circumstances it points out that a strong minority opinion in this country favours the introduction of laws to make venereal diseases notifiable and treatment compulsory

From the evidence collected by this commission and that available from other sources it seems to be established that the incidence of syphilis has declined in this country but it will be agreed that the rapidity of the decrease is hardly commensurate with the ease with which patients may be rendered non infectious by modern methods of treatment The success achieved compares unfavourably with that in countries where social control is more vigorous and the question may be asked how far the arguments against compulsory notification and penalisation of the delinquent are still valid There are nowadays so many incursions into the personal liberty of the subject that it is by no means certain that the provision of limited powers to coerce the infectious defaulter or the neglectful parent would cause resentment A clue to the popular feeling on this point was provided a short time ago In 1934 a questionnaire[2] was submitted to patients attending the Salford municipal clinic for the treatment of venereal diseases, inviting expressions of opinion on two points (1) Should a person suffering from a venereal disease be compelled to receive treatment, provided it is given confidentially and free ? (2) Should the parents or guardians of children suffering from venereal disease be compelled to have such children treated under the same conditions ? In reply to both questions there were 429 ayes and 5 noes The opinion among this group of infected people was thus overwhelmingly in favour of some form of compulsion

---

[1] Amer J Syph July 1936 Part 2

Nevertheless, in considering the coercion of non-coöperative or defaulting patients we must not risk losing all that has been gained by the persuasive approach The risk is that minatory regulations will drive the disease underground, and this risk is far greater in England than, for example, in the Soviet Union where venereal diseases are regarded as diseases like other diseases and nobody thinks the worse of a man because he contracts them The conditions are really not comparable But in England and Russia alike the object must be to make the patient realise how much he stands to gain by cure, and a useful illustration of this comes from the social service department of the University of Pennsylvania,[3] where there has been complete freedom to experiment in what Louise Ingraham calls " technics of persuasion " Here as in many other places the aim has been to obtain from the syphilis patient his voluntary disclosure of recent sexual intimates and his services in personally recruiting them for medical examination On this basis persuasion was 92 per cent effective when the individual contact could be personally reached, and this success was independent of the type of community, whether black or white, well to do or indigent Of 201 patients with syphilis it appears that 114 of them identified 174 exposures, being an identification rate of 1 5 contacts per productive case Possibly, the author admits, a more aggressive technique would give greater immediate reward, but at the same time it would almost certainly sacrifice future gains Father O'Flynn, who had a way with him, did however sometimes coax the lazy ones on with a stick

ANNOTATIONS

GREAT ALTITUDE

AT a time when the sport of mountain-climbing is attracting every summer a larger crowd of devotees especially in England and Germany, any sound research into the medical aspects of great altitude must have a practical interest A more serious importance comes from the growing conviction that aeroplanes are likely to fly at increasingly greater heights, and the recognition of anoxæmia as a factor in pulmonary and circulatory disturbances

On the firm foundations built at Oxford by Haldane, Douglas, Priestley and their co workers, there is arising a superstructure, much of the work on which has been done in America It is possible that there is lacking in the United States the coördinating influence of Barcroft over the Cambridge school But the Americans are fortunate in having high mountains near at hand, a circumstance which has given to much of their work a very practical bent Somervell Raymond Greene, and others in this country have written of the digestive disturbances and failure of appetite accompanying the many efforts which have been made to climb Everest Recently working in a steel chamber, Van Liere[1] has shown that at only 14,000 feet there is an average prolongation of the emptying time of the stomach of 35 per cent the least susceptible subject showing a prolongation of 13 2 per cent The delay is caused by a loss of motility, which may be due to the increased output of adrenaline during anoxæmia It will be recalled that medical officers of various Everest expeditions have laid stress upon loss of appetite as a possible factor in the degeneration noted after prolonged residence above 20,000 feet, but it has generally been held that its influence was not the paramount cause From this point of view, the new work of Talbott and Dill,[2] of Harvard, is of importance They describe a disease, first reported by Monge, and named after him, which develops after residence over many years at such altitudes as 15,000 feet It seems probable that though Monge did not observe it in anybody who had lived in the highlands for less than two years, it might appear much sooner at a greater altitude Talbott and Dill give as its symptoms headache, hoarseness, loss of appetite, weakness, paræsthesiæ, and transient spells of stupor, and, as its signs, cyanosis, pigmentation, generalised vasodilatation, and hypotension Some, though not all, of these signs and symptoms have been observed in climbers suffering from altitude deterioration The exact ætiology of the disease is unknown, and in discussing it Talbott and Dill pay, perhaps, too little attention to the work of Argyll Campbell

The time seems ripe for trying to elucidate this and many kindred problems of growing importance Everest was almost climbed in 1933 In 1936 through no fault of the climbers, the expedition was a fiasco A repetition of this fiasco, due to weather conditions, can never be excluded Yet if the last expedition had included a scientific programme it would have produced some solid return for the many thousands of pounds expended It is not enough that the medical officer should pursue a line of research of his own he is usually one of the climbers he has a gigantic responsibility for the health of the party which must absorb most of his mental energy and he may even himself be suffering from the clinical abnormalities which he is attempting to describe If the necessary separate fund can be raised the next Everest expedition should take in its train an independently financed scientific group This should include not only physiologists but clinicians as capable as the medical officers of past expeditions of observing the reactions of their companions to the abnormal environment but like Lord Nuffield's professors freed from the responsibilities of practice

VARIATION IN ANIMAL VIRUSES

VARIATION in filtrable viruses has been known nearly as long as the viruses themselves Almost before the conception of filter passing viruses had taken shape and certainly before it was generally recognised Pasteur demonstrated that a variant of the virus of rabies could be produced, and as every one knows employed it in the prophylaxis of human infection The adaptation of the virus of small pox to growth in the tissues of the calf resulting in the fixed variant vaccinia also belongs to the early history of viruses And since that time especially in the last decade many more examples of virus variants have been brought to light Some of these have been discovered more or less by accident—for example the necrotic variant of Shope's rabbit-fibroma virus—but most have been sought intentionally often with specific prophylaxis in view

In a long and well-documented paper the whole question of variation in animal viruses has lately been reviewed at length by Findlay[1] Much of Findlay's work on viruses has been concerned with the production of variants and a study of their properties so that he is peculiarly fitted to write such an article and he has done it extremely well Starting with an enumeration of all the available facts concerning virus variants he briefly reviews our knowledge of variation in multicellular and unicellular organisms and finally considers the application of this to viruses Naturally it is harder to study variation in viruses than in multicellular organisms or even unicellular organisms like protozoa for viruses cannot be cultivated apart from living cells As yet it has not been found possible to raise strains of virus from a single virus particle and there appears little likelihood of viruses possessing a demonstrable nuclear apparatus thus making it impossible to distinguish between Lamarckian and genetic variation Nevertheless as Findlay points out the available evidence suggests that there is no fundamental difference between variation in viruses on the one hand and in unicellular and multicellular organisms on the other It is true that the absence of any demonstrable mechanism whereby hereditary characters are transmitted such as exists in higher plants and animals makes the application of the term mutation to some virus variants incorrect and in order to overcome the difficulty it has been suggested from time to time that viruses are themselves genes that they have arisen from higher forms and that as the result of highly specialised parasitism all structure and function other than that associated with the hereditary characters has been lost This however is pure hypothesis with little to commend it and it seems more reasonable to assume that in such primitive forms of life as viruses any such specialised medium for the transmission of heritable characters has not been developed That viruses are living things is strongly supported by the fact that they exhibit this phenomenon of variation Indeed as Findlay says in his conclusions it is hard to explain the facts except by regarding viruses as organised living entities But interesting and important though this aspect of variation in viruses may be there is an eminently practical side to it Virus variants have proved their value in the active immunisation against virus infections; in recent years we have seen them used with success in the prophylaxis of yellow fever and horse-sickness and no doubt the near future will provide further examples It is this side of the problem quite apart from the academic one which will ensure adequate attention being paid to this interesting question of variation in viruses

THE SAFETY OF PREMEDICATION

THE use of formidable accessory agents given before the anæsthetic proper is so frequent at the present time that it is important to know what if any disadvantages may accompany the many undoubted benefits which the practice confers on most patients. Dr Dawkins in order to determine the answer to this question contrasts[1] two series of patients, the first operated on between 1921 and 1925 and the second between 1931 and 1935 Each series comprised more than three thousand operations, and altogether he has for his study analysed the histories of over 16 000 anæsthetics given at several London hospitals and in private practice Conclusions drawn from a study of this dimension are worthy of serious notice and perusal of this little work gives information with regard to almost every complication that has been associated with anæsthesia. The matter is well arranged and tabulated so that the author's findings are easily perceived His final conclusion is that during the last five years definite progress has been made towards the reduction of anæsthetic complications Injudicious use of basal narcosis however increases the risk of pulmonary troubles. Some of the figures in the many tables provide an interesting study Generally speaking they agree with commonly held opinion both as regards mortality and morbidity For example the hope that spinal anæsthesia might save patients from lung trouble not infrequent after inhalation a hope long since dissipated is here again shown to be without foundation Pulmonary morbidity is shown by the author at 11 5 per cent after spinal anæsthesia and at 5 9 per cent after ether Chloroform shows the same pulmonary morbidity as ether but the number of patients is so small that much value cannot be placed on this conclusion

CATGUT SENSITIVITY

THERE are still many problems that await solution in the use of catgut as material for ligatures Examination of a wound that has broken down occasionally reveals absorption of the catgut in a fraction of the time stated by the manufacturers Local reaction to the presence of the catgut also occurs most unexpectedly in some presumably clean wounds followed either by delayed healing or by disruption Dr C J Kraissl of New York has thrown light[2] on these problems by his investigations into defects in the structure of catgut and by his demonstration of the possibility of catgut sensitivity Using a carefully constructed apparatus he tested the absorption time of various specimens of catgut Occasionally a strand of catgut was absorbed within a few hours instead of taking its usual time of several days Examination of specimens of catgut revealed that fraying of the strands at the sites of bends occurred In other samples comparatively large foreign bodies of some apparently amorphous material were found twisted into the gut Such defects may obviously alter the rapidity of digestion in the tissues, and Kraissl considers that each strand as used should be examined Packing of catgut in small glass tubes he regards as unsatisfactory The dehydration of catgut which is necessary to render it boilable has two disadvantages It leads to more ready absorption in the tissues, and it decreases the flexibility of the product For these reasons Kraissl thinks we should be content with non boilable gut, and with sterilisation of the gut in the glass tube by germicidal solutions Chromicised gut is largely used Intradermal tests have shown that some patients are sensitive to chromic acid and this may account for failure of healing in certain instances Sensitivity to the protein of the catgut itself may be an even more important factor Kraissl has actually sensitised guinea pigs and subsequently obtained disruption of wounds sutured with catgut He suggests that in the human subject a previous operation is sometimes the sensitising process By cutaneous tests he found that allergic patients were quite often sensitive, in a series of patients tested the highest incidence of sensitivity was in a group who had presented disruption of wounds He suggests that, if catgut is to be used in individuals who have a history of allergy, previous operations, or exposure to chromic acid, appropriate skin tests would be a useful safeguard.

A WORLD ENCYCLOPÆDIA

FROM the bacillus which turned animals blue to fighting aeroplanes Mr H G Wells has foreseen so much which at the time seemed impossible that his latest proposal will be received with respect as well as interest It is nothing less than a series of volumes in which the ordinary citizen would, without any great toil or difficulty, find in clear understandable language, and kept up to date, the ruling concepts of our social order, the outlines and main particulars in all fields of knowledge, an exact and reasonably detailed picture of our universe, a general history of the world, and references to the primary sources of knowledge[1] With the reasons which have led him to suggest this enterprise and their validity everyone will be in sympathetic agreement We live, he says, in a world of unused and misapplied knowledge and skill, and those who are mainly responsible for modern knowledge are often dismayed to find it so ineffective, those who direct the affairs of the world do it without having the relevant information and even without making use of what they do know To cure or at any rate alleviate the trouble he says that we must bring together an account of what is known which shall be available to everybody He is, rather unjustly, a little contemptuous of what has already been done in the way of encyclopædias they are collections of disjecta membra without the coherence which is needed for adequate synthesis and the articles may be neither authoritative nor impartial He wants statements which have been agreed to by representative experts under the guidance of an ad-hoc body which might be called the Encyclopædia Society that would be responsible for getting the necessary revisions made and published and indeed for persuading divergent opinions to come to some agreement The substance of the book would, we gather, be as much quotation as fresh writing It seems indeed that Mr Wells contemplates the extension of his own 'Outline of History" to all knowledge, but the only indication he gives of the scale is the remark that the ordinary citizen might have the encyclopædia in his own home

For a common man it is difficult to take such a panoramic view as seems to come easily to Mr Wells and most of us will naturally think of his proposal with reference to our own special subjects Medicine is a comparatively narrow field, and it is cultivated with an interest and diligence which are possibly rather exceptional. But even here everyone will agree that synthesis would improve the situation, physicians, surgeons, gynæcologists, and the rest keep fairly well in touch with one another through hospitals, journals, meetings, and patients But how do they maintain contact with biology, physics, physiology, and the other institutes of medicine? And when it comes to making medical knowledge effective in daily life we surely see many gaps and much delay, not the fault of the specialists who know but of those who have to try to guide the horrid tangle of social life It seems as near certain as may be that diphtheria is preventable, yet 36 persons died of it last week it seems clear that people would be better if they drank more milk, but the Milk Marketing Board has led to their drinking less, and so on The rational external observer would probably be surprised that the annual report of the Registrar General, which he might well surmise would be their bible, is not a best seller among medical men But it is unnecessary to elaborate by instances an obvious truth of which the medical profession is well aware they deplore the necessity of so many specialists and the rarity of the general physician who is so useful to patients and they do what is possible to extend the curriculum

It is not however with the position within any group such as medical men that Mr Wells is chiefly concerned, inside the profession synthesis and application are in fact not badly done or at least done better than they might be or used to be But where is a doctor to turn if he wants to know about the causes of poverty, the economics of poultry farming, the nature of X rays, the technique of bread making, the history of roads, the influence of John Wesley, coal and how best to use it? He may well want to do so apart from any natural curiosity, for they are all capable of having paramedical bearings The answer is that he will find most of what he wants in any decent encyclopædia and the rest in an efficient public library, there will likely be a small residuum which he will not find at all because the answer to his particular question is not known It would naturally save him a little trouble if he could turn to his copy of the World Encyclopædia, but however complete that might be we doubt whether Mr Wells's main object would be achieved by its provision The difficulty is not that the information is not in print, but that people will not, or at any rate do not, read it, and his campaign, even if it is not delivered of the encyclopædia, will do good by stimulating a certain number to overcome their reluctance to know what they are about But he also has to meet the difficulties that most people unlike himself prefer details to generalisations and that they greatly mistrust the agreed statements of specialists as bases of action as indeed they have reason to do Mr Wells thinks that man is in danger and that unless he does something to pull his mind together his condition will be desperate It may be so but man has a wonderful capacity for getting out of queer situations and he generally prefers to go his own irrational way The present is not as different from the past as many people think; as in so many difficulties a change of heart is wanted more than a change of technique, and a disinterested reincarnation of the Encyclopædia Britannica would go a long way to nourish it.

---

[1] A Friday Evening Discourse to the Royal Institution Nov 20th 1936 printed in *Nature* for Nov 28th The thesis of this discourse is taken from The Anatomy of Frustration a Modern Synthesis (London The Cresset Press) in which Mr Wells pretends to have found the draft of such a World Encyclopædia and considers its merits

ARTIFICIAL PRODUCTION OF ERGOT

A PROCESS which has been invented and patented in the United States is not only of scientific interest but promises to be of commercial importance For nearly two years past there has been a world shortage of ergot of rye due in the 1935 season to the failure of crops in Spain Portugal and Russia, and in the 1936 season to the civil war in Spain where the larger part is produced Not only have prices advanced to more than four times the normal figures but supplies have at times been so difficult to obtain in adequate quantities that makers of the active principles have found it difficult to keep pace with the demand It is understood that the new substance is a result of the discovery that *Claviceps purpurea* in saprophytic culture develops the active principles which are present in extracts made from the natural sclerotia. Extracts from this artificially produced ergot have the physiological activities and therapeutic value of extracts made from the natural ergot of rye

MEDICAL LIVERPOOL

BRITAIN says Trevelyan has always owed her fortunes to the sea and to the havens and rivers that from the earliest times opened her inland rivers to what the sea might bring To the little market town and coastal port of Liverpool with a population of but 2000 in the seventeenth century it brought the rich trade with the West Indies, the gains of smuggling with the Spanish colonies and the almost fabulous wealth of the traffic in slaves which the kindly merchants of the town delicately called the African trade By the middle of the eighteenth century the population had increased to 18 000 and soon Liverpool was to be the first slaving port of Europe; and in 1740 the newly built Royal Infirmary was officially opened by Edward Earl of Derby But history is not altogether the mechanical unfolding of economic processes and it is good to be reminded that it is made by ordinary day to-day people A Medical History of Liverpool from the Earliest Times to the Year 1920 ' [1] touches general history at an interesting angle even though it is primarily a detailed record of the activities of a town's medical men and nurses and their lay associates It is a lively book to read—as serious as humdrum, as entertaining and as varied as medical life always is Men built hospitals administered them founded a medical school, drove in their carriages practised their craft There were wars murders famine and pestilences Quacks sold their nostrums built rich houses gave their names to streets. Body snatchers were caught and sent to prison and members of a learned society passed a resolution in favour of an alteration in the law so that bodies might properly be available for dissection Throughout the story the tang of the sea blows in—Hugh Owen Thomas practises his orthopædic methods on countless dock labourers and ships workers and diseases peculiar to foreign lands touch the port so nearly that a school of tropical medicine is born

One of the arguments originally put forward in support of the establishment of a medical school in the town was so that the erroneous and popular opinion that there is a great want of clever medical men in Liverpool—so universal in London and current everywhere—will then be satisfactorily refuted We shall then cease to be inundated with such shoals of Welshmen Irishmen and—last and worst of all—Scotchmen.' The latter hope was not realised; and to-day all concede to Liverpool admiration for great accomplishment.

THE SPECIAL AREAS

THE third report of the Commissioner for the Special Areas (England and Wales) [1] is primarily concerned with economic reconstruction in the areas but problems and measures affecting the health of the communities come up incidentally Long continued unemployment in an area may impair health directly or indirectly The direct relation is all too obvious two methods of indirect causation emerge from the report. In the first place while transference is accepted as inevitable and indeed desirable the fact is recognised that it tends to drain an area of much of its best stock: The policy of transfer has a dual nature It provides positive gain for the unemployed man who has the enterprise to start life afresh in a more prosperous district but it has a negative reaction on the special areas through the loss of many of their best men and youths In the second place financial stringency handicaps the work of the local authorities concerned ' The high rate burden and the constant anxiety of local authorities about the means of meeting increasing liabilities with a falling income are steadily undermining the standards of service provided. Merthyr Tydfil has a rate of 27s in the £. An examination of the mortality figures was made for the Commissioner and he states I was much relieved to find that the statistics do not indicate an abnormal situation it must be borne in mind" he adds that these statistics do not tell the whole tale It would be fallacious to assume from them that there is no deterioration in the health of the average man who has suffered a fairly long period of unemployment Personal observation leads me to the conclusion that there is some degree of deterioration of condition in most of such men The financial difficulty of the local authorities in meeting any extension of social and sanitary services has been eased by grants up to 75 per cent of the total cost Such grants have been made towards mental hospitals, voluntary hospitals child welfare centres district nursing open-air nurseries physical training cookery classes a cheap milk scheme in the Rhondda district improvements in water-supply sewage disposal and closet conversion It has been possible for example to provide 27 additional district nurses for the Durham and Tyneside area and 63 in South Wales This report throughout conveys a sense of the human tragedy involved: its most poignant paragraphs deal with unemployment among young persons (Part X) Its perusal will quicken the interest and sympathy of those already familiar with the special areas, and should stimulate others to an awareness of the position

LONDON WATER

THE Metropolitan Water Board has many notable achievements to its credit Not the least is the wisdom it has shown in selecting directors of water examination who can write Houston always had something to say, and said it, and Lieut Colonel C H H Harold is a worthy successor In this respect and in the absence of acrimony and special pleading, the whole series of annual reports differs greatly from those of the three eminent chemists retained by the eight water companies whose undertakings were taken over thirty years ago The task which the Board has set itself—to supply one standard of water only, coliform organisms absent in 100 ml —is no easy one That may be easy enough for undertakings drawing their raw water from upland sources well away from and for the most part above human habitations, but when the sources are rivers passing through large and populous towns, and wells in districts which are suburban rather than rural, it is only by unremitting watchfulness that such an aim can be reached

The work of the Board's laboratories[1] is divided into three sections—bacteriological, biological (or planktonic), and chemical In the bacteriological section an experiment into the possible multiplication of *B coli aerogenes* and other organisms in cisterns and filter beds was conducted

> It was found that filtered Thames water initially containing no coliform organisms in 100 ml and giving an agar count of 30 colonies per ml , kept in a plugged and covered bottle, yielded a considerable increase of saprophytes in 24 hours, which gradually disappeared after 5 to 6 weeks, but no aerogenes The same water inoculated with either aerogenes, communior, grünthal or communis (from 270 to 410 per ml) yielded no aerogenes or communis in 2 weeks and no communior or grünthal in 3 weeks Treated with ozone and similarly inoculated, the aerogenes and grünthal disappeared in 2 and the others in 3 weeks In these samples as in the control saprophytes appeared, and after a few weeks disappeared When sterilised with chlorine so that no residual sterilant was present after 24 hours, saprophytes did not appear, and communior disappeared in 3 weeks, but aerogenes persisted for 10 weeks and grünthal and communis for 7 weeks The same water boiled yielded no saprophytes, but aerogenes increased from 270 to 40,000 in 5 weeks and disappeared in 27 weeks whilst the other organisms were not found after 5 or 6 weeks The water again became negative to MacConkey in from 2 to 30 weeks, the best times being given by the ozonised group

It would appear Colonel Harold remarks, that the viability of coliform organisms is influenced largely by the presence and multiplication of saprophytic survivors, and the extent to which these prevail depends largely upon the efficacy of the initial process of disinfection employed, although there may be other contributory factors

The biological section of the report is of great interest and it appears that Colonel Harold intends to develop a branch of water examination which has been somewhat neglected in this country although Houston and Mr Wilfred Rushton D Sc among others have done useful work Fresh water plankton has been studied more intensively in the United States and Central Europe than in most other countries Colonel Harold gives photographs of a plankton net and sampling bottle regularly used on a motor launch on the Queen Mary Reservoir For reasons which are not clear, lakes and reservoirs are richer than rivers in both phyto and zoo plankton The fact that there are few lakes of any size in this country and that these are relatively far from seats of learning may account for the slow development of ecological as distinguished from morphological studies of fresh water plankton in Great Britain The Freshwater Biological Association of the British Empire in February, 1932, opened a laboratory at Wray Castle on Windermere for the study of that lake On the balance of these two classes depends the probability of trouble arising from unusual tastes and smells or from the blockage of filter beds The vegetable plankton develops from spores by photosynthesis, the carbon dioxide of bicarbonates supplying what carbon is required, whilst nitrogen and mineral constituents are obtained from nitrates and other salts dissolved in the water As the algal flora develops pasturage becomes available for the animal population Increase of both kinds of plankton can go on until the least plentiful plant foods are exhausted in the water, these seem to be silicates, phosphates, and oxidised nitrogen (nitrates and nitrites) The development of the phytoplankton is also dependent on the effective penetration of the water by sunlight, hence a rather complicated seasonal variation occurs

The study of plankton seems already to be enabling its control by algicides, such as copper sulphate alone or combined with chloramine, to be put on a sounder basis, and should do much to remove the troubles to which Houston so often referred The chemical section, too, is devoting attention to the determination of those minute amounts of constituents which are limiting factors in the growth of plankton

CAUSES OF STERILITY

AMERICAN medicine, with its capacity for organisation, has gone further than the rest of us in the treatment of the childless marriage, and a symposium appearing in the *Journal of the American Medical Association* for Dec 5th is valuable as reflecting present opinion in the United States The first contribution is by S R Meaker, who has done more perhaps than any other physician to call attention to the need for really careful investigation of both husband and wife if children are wanted and have failed to appear In at least 70 per cent of cases of human sterility the cause is not some single abnormality but rather the summation of several factors Some of these may be genital and some may be constitutional, and they are seldom limited to one partner Meaker and his associates state that only about 10 per cent of the husbands and 5 per cent of the wives that consult them for childlessness are free from all objectively demonstrable evidence of infertility In women the four most important gynæcological abnormalities are genital hypoplasia, abnormal viscosity of the endocervical secretions, partial or complete obstruction of the Fallopian tubes, and faulty ovulation The most difficult of these to detect is the last, for no method of examination has been devised that will show whether or not the ovaries actually liberate mature and normal eggs In treatment Meaker would have us correct every factor demonstrated as inimical to fertility A therapeutic approach from several directions gives results far better than those obtained in older days when attention was directed only towards single items. Of these, one of the most important is of course examination of the semen and R S Hotchkiss points out that this is now done not so much to detect absolute sterility as to provide an estimate of the degree of fertility of the male partner This he assesses according to the total volume of the ejaculate *the motility of the spermatozoa the pH of the* semen the number of spermatozoa present and their appearance and the ratio of abnormal to normal forms present Dealing with the operative treatment of sterility in the male, F R Hagner maintains that the use of fine silver wire as a suturing material is an important factor in the success of his modification of the original Martin operation of baso epididymostomy The other points that he brings out are the necessity of ensuring that spermatozoa are present in the head of the epididymis and that the lower end of the vas is patent before carrying out anastomosis The symposium concludes with a consideration of endocrine factors by Richard Chute Inadequate function of the anterior pituitary, the ovary and the thyroid may any of them he says be mainly responsible for sterility Hypopituitarism is the commonest dysfunction recognised and the use of anterior pituitary hormones is most often advisable but thyroid extract may also be very useful According to Chute the injection of gonad substances—i e substitution therapy—not only does not stimulate the gonads but is liable to injure them

THE DANGERS OF BEING ADMITTED TO A CHILDREN S WARD

THAT a young child may suffer more from the effects than from the cause of admission to hospital has given much anxiety to those in charge of children s wards, particularly in fever hospitals Though it is still impossible entirely to prevent the common but dangerous infections much can be done to reduce them by having an efficient staff by the better planning and ventilation and the greater subdivision of wards and by passive immunisation A leading article in our own columns a few years ago[1] was followed by an illuminating correspondence about the abolition of unnecessary risks The result of treating pyloric stenosis was instanced by J C Spence in Newcastle-upon Tyne and by D Paterson in London in private practice a mortality of 1–10 per cent was to be expected while in hospital with a highly skilled staff it might exceed 30 per cent Later in his Milroy lectures for 1935 E H R. Harries[2] spoke of the overwhelming importance of upper respiratory tract infections the need for a staff numerically and technically adequate to cope with their special dangers and the reforms required in architecture and administration While some still believe that well planned large wards can be efficient as well as economical the majority have as an ideal the small ward unit with one or two beds in each cubicle as in Hutinel s boxes famous since the beginning of the century In these a ward was subdivided by glass partitions into two bed cubicles each with its own window and equipment. This method will prevent all infections except from the early stages of measles and especially of chicken pox for which complete separation and a epsi would be necessary In an ordinary ward the simple barrier system of isolation is effective as described recently by C C Okell and S D Elliott[3] Prevention largely depends on the space between beds but even with the regulation three feet B F Schlesinger found[4] that the simple expedient of placing beds alternately from head to foot was alone enough to ensure that cases remained sporadic which in the past would have led to minor epidemics Better recognised than droplet infection although no less to be feared is the gastro enteritis of infants which can only be avoided by the efficiency of the nursing staff As D Nabarro and A G Signy have suggested[5] the most important precaution is a staff large enough to ensure that no nurse is responsible for more than one or two patients that no nurse should handle stools who has to prepare meals and that the working hours should not be so long that standards are relaxed

At his hospital in Paris Prof Robert Debré has organised a special service for the prevention and detection of cross infection and has put at its head a whole time medical officer with special clinical and laboratory qualifications for his task Largely owing to his initiative a special committee was appointed by the Academy of Medicine to study the problem and the Academy have now passed certain resolutions embodying its principal findings Separate cubicles, they recommend should be adopted by all children s hospitals. In addition steps ought to be taken to prevent contacts in the special departments among the young in patients and between these and children coming from the outer world As Prof Debré pointed out the meeting of children at these cross roads is a most pernicious source of intra hospital infections Stricter measures than heretofore are to be taken in the prophylactic discipline imposed on the nursing and medical staff and on medical students It is essential for these to wear overalls and masks and to be forbidden indiscriminate access to the cubicles of particularly delicate infants Visits by relatives should also be forbidden in infants wards, and should be strictly regulated in the wards of older children In out patient consultations suspect children should be more effectively combed out if necessary by the addition of a supplementary intern. It is particularly recommended by the Academy that all in charge of children s hospital should imitate the reforms already introduced into Prof Debré s hospital where lately the incidence of infections has been greatly reduced

PUBLIC SOCIAL SERVICES

ANYBODY who has the time and inclination to read through a little handbook issued by the National Council of Social Service and now in its seventh edition[6] will be left with a sense that if all local authorities exercised to the full their powers permissive and obligatory no member of the community need ever go uncared for from the cradle to the grave Provision and generally very humane provision, is made for nursing and expectant mothers for infants and children for physical and mental defectives, the destitute the sick and the disabled the aged and the hungry and indeed for every citizen whose circumstances genuinely call for assistance In some cases Scotland is ahead of England for example while education authorities in England may provide meals for needy school-children *at their* discretion in Scotland such provision is laid upon the authorities as a duty and the same is true *of the*

provision of certain kinds of secondary education. The handbook was originally published as a pamphlet in 1917, was revised and enlarged in 1920, and has now again been revised and brought up to date. Besides a comprehensive survey of the social services, including national health and pensions insurance, it contains in concise form an immense amount of information about conditions of industry and employment, the administration of justice in the various courts and a chapter on war pensions and allowances. While the handbook must be invaluable in the offices of public health departments and the various government departments engaged in administering the social services, there will be many other workers, both official and voluntary, who will find it a very useful work of reference.

EXERCISING THE LIVER

It may be contrary to the general rule of rest in active disease to exercise a damaged organ, but it is not necessarily so in all types or at all stages. Since much visceral activity appears to be rhythmical, there is certainly physiological support for applying the principle of alternate rest and work to certain diseased tissues. Prof Pribram has suggested an interesting and novel therapeutic method, based upon his work on liver cell function, in which rhythmic rest and work can be made to improve functional activity in an organ like the liver. From his study of hepatitis, both with and without gall bladder disease, he believes œdema of the liver, to which a great part of the clinical enlargement is due, to be an important feature of these conditions. The improvement noticed after intravenous injections of hypertonic glucose solutions is due not so much to the action of the glucose itself as to the withdrawal of fluid by osmosis from the liver depôts, for a similar diminution in size can be obtained by using hypertonic saline. Many livers seriously diseased, as in cirrhosis, and with grossly impaired function, are not deficient in glycogen, and treatment with glucose, with or without insulin, must clearly have its limitations. For one thing the optimum benefit is likely to be reached quickly, since a liver deficient in glycogen will quickly replenish its stores under treatment, and further improvement in function may cease when maximum storage is reached. In the hope that certain types of liver disease, especially cirrhosis, might respond to stimulation as well as to "protection" by glucose, Prof Pribram has tried the effect of alternately increasing and diminishing glycogen activity—and perhaps other activities—by using insulin and thyroxine on different days. The anabolic or resting phase is produced by the injection of 20 c cm of a 40 per cent glucose solution with 8 units of insulin, the katabolic phase by 1 c cm of 1/1000 thyroxine solution intramuscularly. By these two opposing treatments he believes that the functional activity of the liver cells is raised, and from his results it seems that his hopes are well founded. As one means of estimating the effect of this "Zell-gymnastik" Prof Pribram has studied the water balance in cases of cirrhosis of the liver, and the diuretic effect of the treatment appears greatly to outweigh that produced by either insulin glucose treatment alone, or any other method he has tried, including of course such mercurials as Salyrgan. In general Prof Pribram has applied these original methods to cases of liver œdema and enlargement, but he suggests that the principle involved may be applied to other organs and other diseases. This work is one that will arouse interest and it should lead to further research. Clearly criticisms are not hard to make, but at least it may help in questioning the view that all rest and no work must be the best treatment for diseased viscera.

A WORD TO CONTRIBUTORS

NATURE of her abundance is always creating new varieties, new species, new methods; with every passing year each animal and plant tends to become less like its ancestors and less like its cousins. The same thing happens to scientific journals; they grow different in appearance and they eat different food. This is awkward for those who feed them, and contributors are often heard to complain, for example, that a form of references demanded by one journal will be rejected with contumely by another. In these circumstances the publications committee of the Royal Society has been trying to devise a basal diet that all will accept, and has been asking editors in this country to give up some of their peculiar fads and adopt henceforward the Harvard System of Bibliographical Reference, with whatever local modifications may be necessary to make it palatable. This we have done at the beginning of the New Year, and we have taken the opportunity at the same time to issue a small supplement, "On Writing for THE LANCET," which we hope may be useful as a cookery manual for those who obligingly keep us alive.

FURTHER EXPERIENCE WITH DIVINYL ETHER

DIVINYL ether, vinethene, has not been used by anæsthetists long enough for its exact value to be clearly demonstrated. The publication of the paper concerning over 2600 administrations is a step towards this end. In *Anesthesia and Analgesia* for September–October, 1936, G W Black makes plain both the limitations and the peculiar advantages of the drug. It is obvious that, as was anticipated, vinethene unaided is not a good anæsthetic for long operations requiring full relaxation. Black disapproves of it in these conditions because of its extreme volatility and the difficulty in consequence of preserving a level plane of narcosis. Other authorities have disliked long administrations because of their anxiety about untoward effects on the liver—though Wesley Bourne has shown that, experimentally at least, these fears are groundless. On the other hand for short-operations vinethene has many attractions. It is remarkably quick in its action, is not nearly so irritating as ethyl ether, and produces better relaxation than nitrous oxide, recovery being almost as quick and complete. Experience is needed before the best can be got from vinethene, especially as the signs of anæsthesia are not precisely the same as those usually relied on; for example, anæsthesia may be perfect with a rolling eyeball and an active lid reflex. It has to be given with very free dilution by air or oxygen, and it is admirably adapted for the induction of anæsthesia in children.

Dr Harrington Sainsbury, who died on Dec 20th in his 84th year, was consulting physician to the Royal Free and City of London Hospitals. He took a lifelong interest in the action of drugs and the principles underlying their administration, and wrote on the subject with charming erudition.

A SPECIAL conference of local medical and panel committees has been called for Jan 7th to discuss the capitation fee payable for young persons to be brought under National Health Insurance by the Government's new legislation (see THE LANCET, Dec 5th, 1936 p 1340). A note on the proposals appears on p 60.

PRINCIPLES OF MEDICAL STATISTICS

I —THE AIM OF THE STATISTICAL METHOD

Is the application of the numerical method to the subject matter of medicine a trivial and time-wasting ingenuity as some hold or is it an important stage in the development of our art as others proclaim ?

WHATEVER may be our reactions to that question propounded by Prof. Major Greenwood in these columns[1] fifteen years ago it must be admitted that in the years intervening between 1921 and to day there has been a substantial increase in the number of papers contributed to medical journals of which the essence is largely statistical Not only does there appear to be an enhanced knowledge of and respect for the national registers of life and death which the Registrar Generals of the United Kingdom annually publish and analyse but there is an increasing number of workers who endeavour to apply numerical methods of analysis to their records obtained in clinical medicine The great majority of such workers however have had, naturally enough little or no training in statistical method and many of them would find the more mathematical methods of the professional statistician as has been said obscure and even repellent Often enough indeed the argument is put forward that the use of such mathematical methods is quite unjustifiable that the accuracy of the original material is not sufficient to bear the weight of the treatment meted out to it This assertion is not strictly logical If a collection of figures is worth a statistical analysis at all it is obviously worth the best form of statistical analysis—i.e the form which allows the maximum amount of information to be derived from the data

Whether mathematical statistical methods *are* the best form in particular cases or may be regarded as an unnecessary elaboration must turn rather upon this question : Can we in any of the problems of medical statistics reach satisfactory results by means of relatively simple numerical methods only ? Or upon this question Can we satisfactorily test hypotheses and draw deductions from data that have been analysed by means of such simple methods ? Personally I believe the answer to these questions is an unqualified yes, that many of the figures included in medical papers can by relatively simple statistical methods be made to yield information of value that where the yield is less than that which might be obtained by more erudite methods which are not at the worker s command the best should not be made the enemy of the good and that even the simplest statistical analysis carried out logically and carefully is an aid to clear thinking with regard to the meaning and limitations of the original records If these conclusions are accepted the question immediately at issue becomes this : Are simple methods of the interpretation of figures only a synonym for common sense or do they involve an art or knowledge which can be imparted ? Familiarity with medical statistics leads inevitably to the conclusion that common sense is *not* enough Mistakes which when pointed out look extremely foolish are quite frequently made by intelligent persons and the same mistakes or types of mistakes crop up again and again There is often lacking what has been called a statistical tact which is rather more than simple good sense That tact the majority of persons must acquire (with a minority it is undoubtedly innate) by a study of the basic principles of statistical method

It is my object in these articles to discuss these basic principles in an elementary way and to point out by representative examples taken from medical literature how these principles are frequently forgotten or ignored. I very much fear that the discussion will often appear too simple and that some of the mistakes to which space is given will be thought too futile to need attention I am only persuaded that such is not the case by the recurrence of these mistakes and the neglect of these elementary principles a feature with which every professional statistician is familiar in the papers submitted to him by their authors for counsel s opinion.

Definition of Statistics

Whereas the laboratory worker can frequently exclude variables in which he is not interested and confine his attention to one or more controlled factors at a time, the clinician and social worker have to use records which they know may be influenced by factors which they cannot control but have essentially to be taken into account. The essence of the statistical method lies in the elucidation of the effects of these multiple causes By statistics therefore we mean quantitative data affected to a marked extent by a multiplicity of causes and by statistical method methods specially adapted to the elucidation of quantitative data affected by a multiplicity of causes (G U Yule: An Introduction to the Theory of Statistics 1927) For example suppose we have a number of children all of whom have been in contact with measles and to a proportion of them is given an injection of convalescent serum We wish to know whether the treatment prevents the development of a clinical attack. It is possible that the risk of developing an attack is influenced by age by sex by social class and all that that denotes, by duration and intimacy of contact by general state of health A statistical analysis necessitates attention to *all* these possible influences We must endeavour to equalise the groups we compare in every possible influential respect except in the one factor at issue—namely serum treatment If we have been unable to equalise the groups ab initio we must equalise them to the utmost extent by the mode of analysis As far as possible it is clear however that we should endeavour to eliminate or allow for these extraneous or disturbing causes when the experiment is planned in a carefully planned experiment we may determine not only whether serum is of value but whether it is more efficacious at one age than another &c It is a serious mistake to rely upon the statistical method to eliminate disturbing factors at the completion of the work No statistical method can compensate for a badly planned experiment

Planning and Interpretation of Experiments

It follows that the statistician must be able to advise upon the statistical lines [illegible] such as that referred to above should follow Elaborate experiments can be planned in which quite a number of factors can be taken into account statistically at the same time (R A Fisher The Design of Experiments 1935) I[illegible] possible to d[illegible] such methods here and [illegible] is confined t[illegible] type of simple [illegible] out with [illegible] medical workers [illegible] Limitat[illegible] discussion to that [illegible] be tak[illegible] that it is the best form of experiment in a particular case.

---

[1] Medical Statistics (1921) *Lancet* 1 985

The essence of the problem in a simple experiment is, as emphasised above, to ensure beforehand that, as far as is possible, the control and treated groups are the same in all *relevant* respects. The word relevant needs emphasis for two reasons. First, it is obvious that no statistician can be aware of all the factors that are, or may be, relevant in particular medical problems. From general experience he may be able to suggest certain broad disturbing causes which should be considered in planning the experiment (such as age and sex in the example above) but with factors which are narrowly specific to a particular problem he cannot be expected to be familiar. The onus of knowing what is likely to be relevant in a specific problem must rest upon the experimenter who is, presumably, familiar with that narrow field. Thus, when the statistician's help is required it is his task to suggest means of allowing for the disturbing causes, either in planning the experiment or in analysing the results, and not, as a rule, to determine what *are* the relevant disturbing causes.

The second point that must be observed as regards the equality of groups in all relevant respects is the caution that must attend the interpretation of statistical results. If we find that Group A differs from Group B in some characteristic, say, its mortality rate can we be certain that that difference is due to the fact that Group A was inoculated (for example) and Group B was uninoculated? Are we certain that Group A does not differ from Group B in some other character relevant to the issues as well as in the presence or absence of inoculation? For instance, in a particular case, inoculated persons might, on the average, belong to a higher social class than the uninoculated and therefore live in surroundings in which the risk of infection was less. We can never be *certain* that we have not overlooked some relevant factor or that some factor is not present which could not be foreseen or identified. It is because he knows a complex chain of causation is so often involved that the statistician is, as it appears to many persons, an unduly cautious and sceptical individual.

The reason why in experiments in the treatment of disease the allocation of alternate cases to the treated and untreated groups is often satisfactory, is because no conscious or unconscious bias can enter in, as it may in any selection of cases, and because *in the long run* we can fairly rely upon this random allotment of the patients to equalise in the two groups the distribution of other characteristics that may be important. Between the individuals within each group there will often be wide differences in characteristics, for instance in body weight and state of health, but with *large* numbers we can be reasonably sure that the numbers of each type will be equally, or nearly equally represented in both groups. If it be known that certain characteristics will have an influence upon the results of treatment and on account of relatively small numbers the distribution of these characteristics may not be equalised in the final groups, it is advisable to extend this method of allocation. For instance alternate persons will not be treated but a division will be made by sex, so that the first male is treated and the second male untreated, the first female is treated and the second female untreated. Similarly age may be equalised by treating alternate males and alternate females at each age or in each broad age group if individuals whose ages are within a few years of one another may in the particular case be regarded as equivalent.

AN EXAMPLE

Even if in planning the experiment factors such as age and sex have thus been equalised in the two groups, the analysis of the results should never be directed only to the effects of treatment upon the totals. It is possible that treatment may be more effective at one age than at another and this difference will be lost sight of if the groups as a whole are alone compared. As far as the number of observations allow, comparison should be made between sub groups differentiated by any factors that may be of importance. As an example of this experimental method and analysis may be cited the report of the Therapeutic Trials Committee of the Medical Research Council on the serum treatment of lobar pneumonia (*Brit med J* 1934, 1, 241). In each of three centres, London, Edinburgh, and Aberdeen, it was arranged that alternate cases taken in order of their admission to hospital should be treated with serum, both treated and untreated being so far as possible in the same wards and under the care of the same physicians. "It was thought better not to attempt a deliberate sorting of cases in respect of mildness or severity, but to trust that the distortion of chance scatter would become almost negligible in a fairly large number of cases." Age, it will be observed, was not equalised in the allotment of cases, and as fatality from lobar pneumonia certainly varies with age the analysis must first show whether the serum and control groups are equivalent in that respect. The random allocation of patients has, in fact, not quite equalised the groups in that factor. Taking the figures for London and Aberdeen (in Edinburgh the method was not fully carried out) and combining Types I and II, the numbers in two broad age-groups were —

Age	Number of patients		Percentage in each age group	
	Controls	Serum treated	Controls	Serum treated
20–40	104	123	65	75
40–60	55	40	35	25
Total	159	163	100	100

Roughly 35 per cent of the control cases were of ages 40–60 and only 25 per cent of the serum treated. It follows that the comparison of results must essentially be made within, at least, these two age groups. If a lower fatality rate is found in the serum treated when the total groups are compared, this result may merely be a reflection of the fact that 10 per cent less of these patients belonged to the ages at which fatality is normally higher and, correspondingly, 10 per cent more belonged to the ages at which fatality is normally lower. In other words, as the method of allotment has not equalised the groups in an important respect with regard to fatality, the method of analysis must do so.

It is impossible to ignore the fact that in the random allocation of patients to the treated and untreated categories a difficult moral issue is often raised. The treatment is usually based on a priori evidence which suggests that it should have some curative effect. Can it then be justifiably withheld from any patient? And if it is withheld how extensive a trial is justifiable? There are no easy answers to these questions There can be no doubt that any new therapeutic measure *should* be given a period of trial before coming into general use If the results of such a measure are dramatic in the light of all past experience then clearly the trial period will not need to be prolonged But one must be careful of the interpretation of dramatic ; it must imply *something strikingly different from all previous* experience not merely a run of a few successes where some failures might well have been expected Such dramatic events are unfortunately the exception More usually the effect of the new measure will be relatively small though none the less important and therefore its presence (or absence) be difficult to detect in small-scale tests Such tests may well give contradictory and confusing answers They may enable a useless measure to hold for years a position it does not merit (sometimes perhaps to the exclusion of more worthy measures) they may even prevent a really valuable form of treatment obtaining the general recognition it deserves A well planned and extensive trial (such as has been *carried out with measles serum) would obviate* such undesirable results and thereby possibly save more suffering in the long run than is incurred in the trial itself and more speedily than the indeterminate results given by inadequate tests would allow

Summary

The statistical method is required in the interpretation of figures which are at the mercy of numerous influences and its object is to determine whether individual influences can be isolated and their effects measured The essence of the method lies in the determination that we are really comparing like with like and that we have not overlooked a relevant factor which is present in Group A and absent from Group B In experiments involving the treatment of a number of patients who are to be compared with controls not given the specific treatment, any deliberate choice of individuals to be treated may lead unconsciously to the treated group differing *from the untreated group in some characteristic* which known or unknown has an influence upon the results If the series of cases is large a random allocation of individuals—e g by cases being alternately placed in the treated and untreated *groups*—may reasonably be relied upon to equalise the two groups in all characteristics except the one under examination Such a method of allocation does not obviate the necessity of testing in the statistical analysis of the results whether in fact the groups are equal in all characteristics which are believed to be relevant.

INCIDENCE OF ANÆMIA IN PREGNANCY

INFLUENCE OF SOCIAL CIRCUMSTANCES AND OTHER FACTORS

By W J S REID B Sc M.D Aberd M R C P Lond
HON PHYSICIAN TO ANCOATS HOSPITAL, MANCHESTER AND
JEAN M MACKINTOSH M D Glasg D P H
ASSISTANT MEDICAL OFFICER FOR MATERNITY AND CHILD WELFARE, COUNTY BOROUGH OF STOCKPORT

A SERIES of 1108 pregnant women was examined There was no selection of cases either as to social circumstances or as to parity the patients being those who attended the Stockport corporation antenatal clinics The Haldane hæmoglobinometer was used, and the hæmoglobin estimations were all made by one of us (J M M) The examinations extended over about two years, and were more or less evenly distributed throughout the seasons About half the women were examined in the forenoon and the rest in the afternoon Some 72 per cent of the examinations were made between the twenty-sixth and the thirty-second week of pregnancy and only 7 per cent after the thirty sixth week The age and parity distribution of the women is shown in Table I

Incidence of Hyperchromic Anæmia—In all cases showing a *reading of 70 per cent of hæmoglobin* and under blood films were prepared and examined by one of us (W J S R) No case of pernicious anæmia was found It may be recalled that Evans who examined 4083 patients found no case of severe anæmia

Incidence of Hypochromic Anæmia—Amongst our cases we found that 4 0 per cent gave a hæmoglobin reading of 86 per cent and over 43 9 per cent showed a reading between 70 and 84 per cent and 10 2 per cent gave a reading below 70 per cent Davidson and his colleagues in Aberdeen (1935) in an examination of 810 pregnant women found 17 5 per cent with a hæmoglobin reading below 70 per cent. *Helen Mackay (1935) in London* examined 100 pregnant women and found 4 6 per cent. with a hæmoglobin reading below 70 Boycott (1936) also working in London in a series of 222 cases found 11 per cent of his cases gave a reading below 70 All these workers used the Haldane method American investigators Moore (1929) Lyon (1929) Galloway (1929) Adair Bland Goldstein First (1930) with various methods of estimation examined groups of cases ranging from 100 to 1176 in number and found a much greater incidence *of anæmia in pregnancy They give figures* ranging from 19 to 81 per cent of patients with less than 70 per cent hæmoglobin

TABLE I

Age-group	Parity													Total
	1	2	3	4	5	6	7	8	9	10	11	12	13	
20 and under	75	14	2	—	—	—	—	—	—	—	—	—	—	91
21–25	205	9°	27	12	2	1	—	—	—	—	—	—	—	330
26–30	117	90	79	25	18	11	—	—	—	—	—	—	—	340
31–35	31	40	29	30	28	10	12		4	1	1	—	—	189
36–40	8	10	6	14	11	11	8	3	6	3	3	4	—	96
41 and over	4	1	5	2	0	4	3	2	1	3		—	1	31
Total	440	26	148	80	65	37	23	12	11	7	6	4	1	1108

Effect of Social Circumstances—In order to determine whether economic circumstances had any effect we divided our patients into two groups according to the average income per head of the family per week after deduction of rent Group I comprised those women whose family income amounted to an average of 12s per head per week or less Group II those with an average over 12s per head It was possible to assess the income in each case with a considerable degree of accuracy from office records and the personal knowledge that the health visitors have of each family. For this purpose the pregnant woman is counted as two, so that, for example, when dealing with a primipara, she would be in Group I if the family income after deduction of rent was 36*s* per week or less, and in Group II if over that amount. Table II shows the results of such a comparison.

TABLE II

—		Social group	Total in group	Number below Hb 70	Per cent below Hb 70
Whole series	{	I	710	93	13·2
		II	398	20	5·0
Primiparæ	{	I	211	16	7·6
		II	229	10	4·4
Multiparæ	{	I	499	77	15·4
		II	169	10	5·9

Whether the figures are taken as a whole or divided into the two groups of primiparæ and multiparæ, it is found that the percentage in Group I showing a hæmoglobin reading below 70 is considerably greater than in Group II. It appears, therefore, that the social circumstances have a definite influence on the hæmoglobin readings. This is in accordance with the findings of Bland, Goldstein, and First (1930). Boycott (1936), on the other hand, was unable to find any correlation between the hæmoglobin level and the social circumstances.

Influence of Multiparity.—Bland, Goldstein, and First do not consider that parity has any relation to a low percentage of hæmoglobin. Neither Helen Mackay (1935) nor Boycott (1936) was able to obtain conclusive results.

In our series the percentage of patients giving a hæmoglobin reading below 70 in Group II of both primiparæ and multiparæ is about 5, but in Group I there is a conspicuous difference between the primiparæ and multiparæ—i.e., 7·6 compared with 15·4. To investigate this point further, the multiparæ were divided into two groups, those with two to four pregnancies in one group, and those with five or more pregnancies in the other group. The results are shown in Table III.

TABLE III

—	Per cent. below Hb 70		
	Total	Social group	
		I	II
Primiparæ	5·9	7·6	4·4
2–4 para	12·1	15·1	4·6
5 para and over	15·7	15·5	16·7

When social Group II is studied, it is found that the percentage with a hæmoglobin reading below 70 is about the same for primapara and for those women with two to four pregnancies, but that among the women with five or more pregnancies the percentage with a hæmoglobin reading below 70 is three times as great. Multiparity, therefore, in good social circumstances, appears to begin to exercise a definite effect only when the women have had five or more pregnancies. In poorer social circumstances multiparity appears to have an effect on the hæmoglobin level at an earlier stage. This effect is no doubt accentuated by the fact well known to all social workers that when the economic circumstances are poor, the mother almost without exception sacrifices her own interests to those of the rest of the family. In better social circumstances no such sacrifice is called for.

Influence of Age.—Age is another factor which may be considered. Bland, Goldstein, and First (1930) concluded that age did not influence the incidence of moderate or severe anæmia. Mackay (1935) found no change with increasing age. Boycott (1936) also found no correlation between age and the hæmoglobin level.

To exclude the influence of parity, primiparæ only were considered in this connexion. Two groups were taken: those under 21 years of age, and those of 31 and over. The results are shown in Table IV.

TABLE IV

—		Age	Per cent below Hb 70		
			Total	Social group	
				I	II
Primiparæ only	{	Under 21	8·0	9·5	6·1
		31 and over	6·9	17·6	—

Age seems to have no influence, but the influence of social circumstances is once again manifest.

Effect of Work.—A considerable proportion of women in the north western area work at various trades during pregnancy. In the series 318 women worked outside their own homes during pregnancy, and 790 did their ordinary household work. Of the outside workers, 7·5 per cent had a hæmoglobin value below 70, and of those who worked at home 11·3 per cent had a value below 70. When they are separated into primiparæ and multiparæ, and again subdivided into the two social groups, the difference between the workers and non workers disappears, as Table V shows.

TABLE V

—		—	Per cent below Hb 70		
			Total	Social group	
				I	II
Primiparæ.	{	Workers	5·9	7·2	4·2
		Non workers	5·9	8·1	4·5
Multiparæ.	{	Workers	11·3	14·7	3·4
		Non workers	13·3	15·5	6·4

Again the influence of social circumstances is apparent, and especially among the multiparæ in social Group II, where the influence of the addition of the woman's wage to the family income is clearly shown in the low percentage of those giving a reading below 70.

Influence of Abnormality in Pregnancy.—It was not possible to trace any influence from this cause on the hæmoglobin level.

It is proposed in a further paper to study the influence of the anæmia on the subsequent history of mother and child. So far, from a preliminary examination, we have been unable to trace any influence on the maternal death rate, the stillbirth rate, or the neonatal death rate.

SUMMARY

(1) The hæmoglobin level was estimated in 1108 pregnant women, and 10·2 per cent of them gave a

reading below 70 per cent (2) The anæmia was always hypochromic (3) When the women were divided into two groups according to the family income it was found that the incidence of anæmia was higher in the lower income group (4) Multiparity in good social circumstances did not appear to have much influence except in women with five or more pregnancies (5) Age work outside the home or abnormality in pregnancy had no recognisable influence on the degree of anæmia.

A SOVIET HEALTH RESORT

(FROM A CORRESPONDENT LATELY TREATED THERE)

KISLOVODSK, situated in the mountainous region of the Northern Caucasus has in the past few years become one of the most frequented and highly developed spas of the Soviet Union Large further development is planned for the next ten years including a hotel and sanatorium for foreign visitors The object of this ten years plan of construction is full utilisation of the natural resources of the locality the climate and mineral gaseous springs

The centre of the town is 800 m above sea level, but some of the new sanatoriums are at a height of 1000 m. It lies in a narrow valley protected from the wind on all sides but the north. Its climate is sub alpine and the season is from June to March March, April, and May being rainy months The summer is hot but not oppressive for the nights are always cool. The autumn and winter are dry and sunny and there are more hours of sunshine than at Davos Some sanatoriums close for repairs and spring-cleaning during the rainy months but the spa functions all the year round.

The mineral gaseous water of Kislovodsk *Narzan* was appreciated by the ancient inhabitants of the region, the Abhasians, and was called by them *Nard-san*—i e athlete water Its composition is compared to that of Bad Nauheim narzan having 1 06 g free carbonic acid gas per litre; Nauheim water 3 9; narzan 4 4 g mineralisation and Nauheim 20 10 The main narzan spring gives 2,000 000 litres of water a day An equally gaseous but more highly mineral spring gives 700 litres. Narzan No 1 is bottled as a table water but its great therapeutic use is in baths Narzan No 2 is not used for baths but is considered valuable for certain digestive disorders.

The principal spring has long been protected from pollution and made available for both drinking and baths The first bath house was built in 1803 and one equipped with English porcelain baths still in use was erected between 1910 and 1914; but there were no sanatoriums and no permanent medical service before the end of the Civil War

The planned development of the Caucasian spas along with the other health resorts of the Soviet Union began in 1924 when the All Union Central Organisation of Health Resorts was established in Moscow It appoints a director in each spa who with his staff, controls the medical treatment on the spa territory The four Caucasian spas with their rich and varied mineral and radio-active springs and mud baths are in close touch for medical, research and administrative purposes The local sanatoriums are controlled by various bodies but they conform to the principles of medical treatment laid down by the spa management These principles are based on the research work carried out in the appropriate health resort scientific institute—for instance at the State Central Institute for the Study of Health Resorts at the State Institute of Medical Climatology and Climate Therapy in Moscow or at the State Balneological Institute at Piatigorsk which is the scientific headquarters of the Caucasian spas Each institute publishes the results of its researches in three or four yearly volumes there is a monthly journal of the health resort medical service and conferences of the health resort specialists are periodically called Some sanatoriums also carry on independent research Detailed records of all patients are kept at all sanatoriums and their previous and subsequent health history is available The central organisation coördinates all this work and directs the lines of research.

THE SANATORIUMS AND THEIR PATIENTS

The patients do not themselves pay for the treatment they receive but they may pay for part or all of their board and lodging The trade union or organisation for which a patient has been working pays for his medical treatment and for the balance of his board. The capital expenditure of the spa is covered by State or trade union grants This means that enormous sums are being spent by the State on the development and upkeep of the spas and that this expenditure must be justified by a careful selection of those patients who will benefit most in the shortest time by the treatment that a given spa provides

In each industrial or rural health service organisation a commission of two or three health resort specialists makes the final selection from patients referred to them after considering the value and capacity of every health resort in the Soviet Union Kislovodsk for instance would benefit a very large range of patients by reason of its excellent climate but its water makes it specially suitable for the treatment of diseases of the heart and vascular system, with or without certain nervous disturbances and minor affections of the lungs Acute heart cases those with renal disease and some types of nervous disorder are not sent to Kislovodsk either because they would not profit by it or because they would interfere with the other patients

Though patients can and do get lodgings in private homes or in hostels and receive out patient treatment in the spa clinics this is regarded as a stop-gap arrangement The development of Kislovodsk as a health centre is based on the sanatorium designed to give the patient the utmost comfort and rest and equipped with most or all of the apparatus necessary for treatment

Within the last twelve years some 55 sanatoriums have been established 13 belonging to the Central Health Resort Organisation 14 to different trade unions and the remainder to the various ministries the health ministries of the national minorities particular factories or industries the coöperatives and other organisations Some of the sanatoriums are old villas adapted and enlarged but most are spacious new buildings housing 100–250 patients in rooms with one to four beds, and hot and cold running water, and balconies with couches or easy chairs The allocation of rooms varies according to the management of the sanatorium For instance, in that of the Ministry of Agriculture half the rooms are single, and they are allocated on medical grounds to the patients who would be likely to disturb roommates, in the sanatorium for savants, one of the most luxurious, double rooms are provided only for married couples, and there are a number of suites of two rooms for academicians and in the newest trade union sanatorium for industrial workers the majority of rooms are for three or four, and the few single rooms are generally allotted to children who, for family reasons, are obliged to accompany a parent who is a patient The State Bank workers' sanatorium has nothing but double rooms There is a generous allowance of bath and shower rooms per corridor

Almost every sanatorium has its hydrotherapy department where pine extract and other medicated baths and various douches are given This form of treatment for nervous patients is very widely practised in the Soviet Union In some of the central sanatoriums the narzan water is laid on and the baths can be taken on the premises, but as a rule the patients are transported by motor omnibus from their sanatorium to the central pre war bath house and the new October Baths Both establishments are open twelve hours a day Patients receive a week's supply of tickets giving time of appointment and number of bath cubicle from their nurse at the sanatorium The cubicles are well ventilated, there is a rest room with as many divans as cubicles, and a physician is always in attendance Each sanatorium has its electro cabinet equipped for light treatment galvanisation d'Arsonvalisation, faradisation ionisation and diathermy Most have dentists' consulting rooms, X ray cabinets, and laboratories for clinical tests Neighbouring sanatoriums sometimes share each others' laboratories and X ray apparatus, or the central spa establishments may be used

The sanatorium staff consists of about one doctor for fifty patients besides the sanatorium director, who is generally also chief physician though his duties are mainly administrative, and there are also a number of visiting specialists There are trained nurses always on duty, several masseuses, and at least one gymnastic instructor who has specialised in remedial gymnastics In the new trade union sanatorium for 250 patients there are three gymnastic instructors, and at the time of my visit there were fifteen different groups of patients for remedial exercises An open air sports' ground and indoor gymnasium as well as a gymnastic apparatus room are provided

The sanatorium dining room is generally a light and spacious room furnished with tables for four Three substantial meals and a light tea or supper are provided on restaurant lines—i e , there is a fair choice of dishes and several courses at each meal Each sanatorium has its dietitian and in most cases the head cook has been trained or has had part of his training at Prof Pevsner's dietetic hospital in Moscow Regulations insist that the head cook as indeed all specialists shall be sent to their training institute for refresher courses every year The organisation of diets varies from sanatorium to sanatorium The fullest development is seen in the savants' sanatorium where fourteen basic diets are recognised the tables are numbered accordingly and each dish on the menu has against it the diet number for which it is allowed Happy the patient on diet number fourteen, for he may partake of every dish! The prominence given to dietetics is partly due to the prevalence of intestinal disorders in a country where typhoid and dysentery are still fairly common, and partly to the fact that market gardening and poultry, dairy, and fruit farming are still little developed in the outlying parts of the Soviet Union The spa has had to organise its own "food base" Many sanatoriums have their home farm, but at a considerable distance over unmade roads Cooks must be skilful to produce balanced, tasty, and digestible meals out of somewhat coarse and limited products Moreover patients come from all over the Union, many from places more distant and different in climate and food conditions than even England, from Yakutia, Turkmenistan, Karelia, and Mongolia, for instance, and they need education in choice of food In addition to these considerations much research is being done on the dietetic treatment of rheumatism and gout, and many Kislovodsk patients are being treated for obesity In cases which permit of it the " terrain cure " is used for overweight The great public park is traversed by carefully graded and measured walks, plentifully provided with seats, and leading up the hillsides The doctor's prescriptions may include two daily walks to the Red Sun hill top or one up the Little Saddle

AMUSEMENT AND TREATMENT

Entertainment, considered as culture and education, is organised by a member of the staff, generally one of the gymnastic instructors The big sanatoriums have their concert and dance halls or theatres and cinemas fitted with sound apparatus Films, concert and variety artists from Moscow, Leningrad, and Rostov tour the health resorts Patients from neighbouring sanatoriums are invited in to each others' entertainments, tickets for the central spa theatre and concerts are distributed by the " culture worker " Games, dances and excursions are organised Sanatoriums have their libraries, and chess and billiards are played

Sanatorium régimes vary but are not oppressive Indeed it is the established policy to make the newly arrived patient aware of the possibilities rather than of the restrictions In some sanatoriums children are admitted, in others—generally those belonging to organisations that have their children's sanatoriums—they are forbidden Husbands or wives of patients can usually get a place if they apply in time, even though this practice is counter to the principle, mentioned above, of very careful selection of patients on medical grounds There is a social factor in the selection too The more valuable workers get preference over the less energetic, devoted, and responsible It would be a false economy to separate husbands and wives who want to spend their leave together, and these valuable workers are worth generous treatment A children's playground has been established in the centre of the park by the spa management It is staffed by trained teachers and has provision for a hot midday meal and afternoon rest Children can thus be taken off their parents' hands for a large part of the day Medical examinations and treatments are by appointment, so that patients are spared waiting about Generally they have baths and some other form of treatment on alternate days Meals are served over two hour periods In the afternoons there is a two hour rest period when patients should be either in their rooms or off the premises In some sanatoriums there is lights-out at 11 30 in others there is no fixed bed time On the whole the sanatoriums are quiet. The resident staff generally occupy separate buildings with their families and the domestic staff live in the town The wide carpeted corridors and stairs and general large allowance of space per head seem conducive of tranquillity Both spa and sanatorium directors and patients seemed puzzled when questioned about discipline always replying But they are not children here; they know how to behave ' There is a rule that a patient can be expelled for drunkenness but it would only be enforced for persistent drunkenness and no one could quote a case of this Alcoholic drinks are not served in the sanatoriums but can easily be obtained in the public restaurants and bars The Caucasian wines are much appreciated and patients seemed to be drinking them in moderation but very little drinking of spirits was to be observed Smoking is allowed everywhere but in the dining rooms though of course both alcohol and tobacco may be forbidden to individual patients There was very little evidence in either conversation or behaviour of patients disobeying doctors orders No one said Just this once though of course I m not supposed to On the contrary patients seemed very ready to coöperate with authority and extremely critical of any laxity

The health resorts of the Soviet Union have been termed in official pronouncements the repair shops of the workers This may suggest a somewhat inhuman and mechanical treatment of patients but actually the solicitude for them and the amount of individual attention that each one gets is remarkable The idea is to overhaul the patient as thoroughly as possible in the three to nine weeks of his stay The director of the Ministry of Agriculture s sanatorium pointed out the importance of the dentist s accessibility for his patients Agricultural workers generally live far from a dentist and neglect their teeth We must see to their teeth while they are here and educate them in oral hygiene too Nearly every women patient is referred to the gynæcologist Troubles hitherto unsuspected may be discovered by the day to-day observation of patients at rest and serious developments prevented Patients are encouraged to complain of their minor ailments to the nurse or physician responsible for them and treatment is modified as the patient requires Most patients see their nurse every day She must examine the spa booklet in which all treatment prescribed is entered and make the necessary arrangements for its performance The resident doctors see their patients at least once in six days and on the patient s departure they check his booklet and enter in it necessary recommendations for the future Patients seemed to be enjoying the care and consideration which they received They talked very little of their ailments to each other and a great deal of their pleasure in their beautiful surroundings By the end of their stay they are generally getting a little bored with comparative inactivity and are glad to leave since they now feel better

Kislovodsk is still in its infancy Under the ten year scheme of development the territory of both town and spa will be considerably enlarged A town park and cultural centre will be established apart from the spa park theatres cinemas and concert hall and open air places of sport and entertainment The existing sanatoriums are regarded as too close together this gives a towny effect whereas people should rest and recuperate in the country The defect will be remedied by the removal of the old buildings and the utilisation of the space for gardens. In the future sanatoriums with a space allowance of 250 sq m per head (including garden space) is envisaged Two more narzan springs have been discovered and will be brought into use so that there will be enough water for 17 000 patients at a time to have narzan bath treatment. The number of patients passing through the spa every year will be increased to 200 000 Beautiful perspectives magnificent public buildings and places of refreshment green zones swimming pools and lakes fountains statuary and all the appurtenances of pleasure grounds have been planned in detail as well as the more prosaic matters of sanitation transport cold storage and central heating This comprehensive planning of amenities together with the systematic study of the application of the natural resources and the effects of treatment make Kislovodsk a health resort of exceptional interest and promise

PARIS

(FROM OUR OWN CORRESPONDENT)

COMING REFORMS IN VENÉREAL DISEASE LEGISLATION

M Henri Sellier Minister of Public Health has just issued his draft of a Bill soon to be submitted to Parliament on the prophylaxis of the venereal diseases This Bill has been awaited with much suspense in many quarters the medical profession has dreaded further incursions into professional secrecy and the proprietors of licensed brothels have taken genteel offence at the prospect of their activities being identified with the white slave traffic It is evident however from a first scrutiny of this draft that M. Sellier has enjoyed the aid of diplomatists with a knowledge of human nature and of legal experts intimate with social and medical problems If only half the good intentions expressed in this Bill materialise a great step forward will have been taken towards the control of the venereal diseases There are thirty articles in the Bill but no attempt will be made here to summarise all of them According to the first article, it will be incumbent on a doctor in attendance on a patient of either sex suffering from a venereal disease which is contagious or liable to become so to supplement his prescription with a notice drawing attention to the contagious nature of the disease in question and to the provisions of the new law The second article is concerned with the conditions under which a doctor must notify to the public health authorities the case of a patient who is behaving so as to be a danger to others or himself Later the conditions are defined under which communication of a venereal disease from one person to another is punishable by imprisonment or a fine in an extreme case a term of five years of imprisonment may be inflicted In another article the public health authorities are empowered to demand a medical certificate of any one about whom they have good reasons for suspecting that he or she is suffering from and transmitting to others some venereal disease There follows a whole string of provision calculated to prevent the transmission of syphilis in the act of wet nursing taking into account both alternatives—the infection of a healthy wet nurse by a syphilitic infant and of a healthy infant by a syphilitic wet-nurse

M Sellier s Bill also provides for the continuity of specific treatment the neglect of which by the patient becomes a legal offence He or she may choose between the treatment available at a dispensary or that of a doctor approved by the health authorities, but in either case the treatment chosen by the patient must be submitted to by him Otherwise he or she risks forcible detention in a hospital, discharge from which may require the consent of the authorities Infraction of this rule may qualify for a term in prison not exceeding three months Up to three years of imprisonment may be earned by persons habitually debauching and corrupting persons of either sex under the age of 21, and even if the sufferer is over this age, certain penalties may be inflicted. No one may proceed to the fifth examination for the doctorate of medicine without presenting a certificate indicating that the holder has attended a course of instruction in the venereal diseases approved by the faculty of medicine, a certificate must also be produced stating that an examination referable to these special studies has been successfully passed. Other articles are concerned with remedies and tests No remedy may be sold or employed in a public institution for the treatment of a venereal disease unless it is identical with what has been endorsed by the Ministry of Public Health on the recommendation of the Academy of Medicine Only those laboratories approved of by the public health authorities will be considered as authorised to undertake the necessary serological tests for the diagnosis of syphilis It is stated that when the new law comes into force, all the old administrative machinery concerning the sanitary regulation of prostitution will cease to exist

A NEW MEDICAL SCHOOL BUILDING

The foundation stone of the new buildings of the Paris faculty of medicine was laid on Dec 3rd in the presence of a distinguished gathering representative of the municipal authorities, the University of Paris and the medical profession M Jean Zay, Minister of National Education, presided, and among those present were Prof Roussy, doyen of the faculty of medicine The doyens of the four other faculties, as well as M Charléty, rector of the University, were also present The new buildings, which are to serve the education of medical students in the first two years of their training, are to be built on the site of the Charité Hospital in the very heart of Paris

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

ASCORBIC ACID IN URINE

AT a meeting of the Edinburgh Pathological Club a fortnight ago Drs H Scarborough and C P Stewart described their observations on the estimation of ascorbic acid in urine They said that the amount of indophenol reducing substances in normal urine is increased by boiling with acid in an inert atmosphere and by prolonged treatment with H_2S Study of the rate of oxidation of these substances by atmospheric oxygen and of their regeneration by H_2S suggests that part at least is not ascorbic acid, though it behaves in a somewhat similar way This suggestion is supported by the fact that only part of the indophenol reducing power disappears rapidly when the urine is aerated in the presence of the specific hexoxidase recently studied by Hopkins and Morgan The fact that part of the indophenol reducing power does disappear rapidly under these conditions suggests that ascorbic acid is actually present This conclusion, however, depends upon the absolute specificity of the enzyme, which is not yet fully established The actual quantity of presumed ascorbic acid is greater than that determined by any of the direct titration methods Part of it seems to be present in a combined form (hydrolysed by acid) and part in the dehydro form (reduced by H_2S) The non ascorbic acid substance is not cysteine, glutathione, ergothionine, glycuronic acid, galacturonic acid, nor glucose

MEDICINE AND THE LAW

Proof of Insanity in Criminal Cases

IN R *v* North the Court of Criminal Appeal was asked on Dec 14th to say that a jury might infer insanity even though the defence had offered no specific evidence of it by means of medical or other witnesses North had been keeping company with the deceased girl with her mother's consent Last July the pair went out into the country together Later, the same evening, North stopped a policeman who was bicycling along the road and showed him the fly leaf of his bank book on which was written a short account of the crime He then took the policeman into a field and pointed out the girl's body lying in some long grass Death was due to strangulation and there was evidence of a bruise on the chin Defending counsel, though conceding that there was no medical evidence of insanity, invited the jury to look at the whole story and infer that North was mad at the time Mr Justice Goddard told the jury that there was no evidence on which a verdict of insanity could properly be founded and in effect directed them to disregard that defence On appeal it was argued that neither in North's case nor in any case was a judge entitled to give the jury such a direction The Court of Criminal Appeal however, said that this step was properly within the province of the judge at trial

Expert evidence of insanity is not indispensable, this point was established in R *v* Dart in 1878 But, if the defence of insanity is to succeed, proof must be given, the onus of proving it is on the accused The issue is a question of fact which the jury must determine under the direction of the judge Lord Hewart seized the opportunity in North's case to declare once more the three conditions which accused persons must satisfy if insanity is to be a good defence—the three "stiles" to be surmounted, as he called them in R *v* Anderson (the East Brighton golf links murder) First it must be proved that, at the material time, the accused was suffering from disease of the mind—Stile Number One Secondly it must be proved that, by reason of that disease of the mind, he was labouring under a defect of reason—Stile Number Two Lastly comes a choice of stiles, the accused need not get over both of them, but he must get over one or the other He must prove that, by reason of deficiency due to disease, he either did not know what he was doing, or, if he did know, he did not know that he was doing wrong In North's case, said Lord Hewart the task of the defence had never been so much as begun It may be added that it is not the duty of the prosecution to tender evidence of a prisoner's insanity This point was dealt with by the Court of Criminal Appeal in R v Oliver Smith in 1910 It had arisen earlier over the practice of the Crown calling the prison doctor to prove the prisoner's state of mind At a meeting of the judges it was decided that the Crown should not call evidence of insanity but that any evidence in the possession of the Crown should be placed at the disposal of defending counsel to be used by him if he thought fit

Another Unsuccessful Appeal

On the same day the Court of Criminal Appeal rejected a similar appeal against a conviction for murder where death had been caused by strangling (R v Batty) and where insanity had been mentioned as a possible defence Batty had gone on a half day excursion with the dead girl and in some sort of quarrel he had taken her by the throat Next morning he gave himself up to the police and took them to the field where the body lay There was medical evidence that death occurred quickly and it was contended that there was no evidence that more than one hand had been used The appellant's counsel argued that the trial judge had omitted to refer to these facts which might have justified a verdict of manslaughter instead of murder Lord Hewart said it amounted to a suggestion that the judge had not adequately invited the jury's attention to fragments of the evidence indicating that the accused might not have known the exact length of time for which a person must be throttled in order to cause strangulation There was he said nothing in this argument and the appeal must be dismissed

Battersea Hospital Litigation

The headline Hospital Staff Sensation in a London daily newspaper this week was followed by statements that ten Harley-street and Wimpole street specialists were applying for an interim injunction to restrain the Battersea General Hospital from dismissing them from its honorary staff Recent changes in the name and objects of the Battersea General Hospital, eliminating the element of anti vivisection were discussed in THE LANCET a year ago (Nov 30th 1935 p 1245) It was subsequently decided that all the appointments at the hospital should be thrown open to public competition An independent body was asked to select a new staff from those who applied and some of those members of the old staff who were not reappointed are contesting the legality of what has been done No comment can be made on the situation without trespassing on matters which are now sub judice but any proceedings which elucidate the legal position of the honorary members of hospital staffs will naturally be of interest to the medical profession

---

PSYCHIATRIC DEMONSTRATIONS —The senior medical staff of the Maudsley Hospital are coöperating with Dr Desmond Curran in giving psychiatric demonstrations at St George's Hospital to alternate with the neurological demonstrations held by Dr Anthony Feiling at 5 P.M. on Thursdays. The following have been arranged for next term: Dr Curran (Jan 14th) Dr Aubrey Lewis (Jan 28th) Dr W H Hubert (Feb 11th) Dr E Guttmann (Feb 25th) Prof E Mapother (March 11th) and Dr Lewis (March 25th) Dr Hubert will deal with the problems of child psychiatry and the other lecturers with psychiatric problems of adult life These demonstrations are not confined to students of the hospital, and further information may be had from the dean.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg Lt A E. Flannery to be Surg Lt -Comdr

Surg Lts (D) W L. Mountain to *Royal Sovereign* and H C Brewerton R. D Johnston and G P Pearse to *Pembroke* for R.N B

A Greenwich Hospital pension of £50 a year has been awarded to Fleet Surg C S Facey M.B retd in the vacancy created by the death of Surg Capt P E Maitland retd. on Dec. 1st.

Applications are invited for appointment to commissions as Dental Officers in the Royal Navy Candidates who must be below 28 years of age on the day of entry must be British subjects of pure European descent

Selected candidates will be entered for short service (six years) in the first instance and on its termination they will receive a gratuity of £1000 unless granted a permanent commission

Application forms and a pamphlet showing regulations for entry and conditions of service rates of pay, &c may be obtained from the Medical Director General of the Navy Admiralty S W 1

ROYAL NAVAL VOLUNTEER RESERVE

Surg Lt -Comdr C H A. Fido to *Drake* for R N B

Surg *Lts C A Mather and W D Williams promoted* to Surg Lt Comdrs.

Proby Surg Sub Lt. L Foster to be Surg Sub-Lt

ROYAL ARMY MEDICAL CORPS

The following appointment has been approved for the year 1937

To be representative Colonel Commandant of the R.A.M C :—

Major-General W H S. Nickerson V C C.B C.M.G., M.B Colonel Commandant R.A M C.

Maj A. L. Robertson O.B E to be Lt -Col

Short Serv Commissions Lt K. H. Foster resigns his commn.

Major E F W Mackenzie O.B.E M.C R A.M.C. has been awarded the Parkes Memorial Prize 1936 for his investigations into the ammonia-chlorine process of water purification in the field, coupled with research carried out by him in connexion with food-supplies in India

ROYAL AIR FORCE

Flight Lt. J H Cullinan is placed on the retired list at his own request

Flight Lt. A. E. Vawser is removed from the Royal Air Force

Flying Offrs D W I Thomas, R F Courtin and D J Dawson to Princess Mary's R.A.F Hospital Halton; P A Lee to Home Aircraft Depôt Henlow; A R Sibbald to No 5 Flying Training School, Sealand; R. H Pratt and E. W R. Fairley to R.A F Hospital Cranwell; J Conroy to No 7 Flying Training School, Peterborough; N P R. Clyde to No. 1 Flying Training School, Leuchars; and C E G Wickham to R.A F Station, Manston.

DEATHS IN THE SERVICES

Lieut.-Col. JAMES TIDBURY R.A.M C. (retd) who died on Dec. 22nd at Woking in his 85th year was educated at University College London and Queen's College Cork, and qualified M.D R U I in 1877 In the following year he joined the R.A.M C served with the Egyptian Expedition of 1882 being present at the battle of Tel-el Kebir and receiving the medal with clasp and the bronze star Retiring in 1898 he was re-employed from June 1915 during the European War and was awarded the O B E.

WE regret to learn of the death of Dr Percy Vernon Davies medical superintendent of the Kingston and District Hospital which occurred on Christmas Day as the result of blood poisoning Dr Davies had been attached to the hospital for 25 years being superintendent during most of the period. Owing to the situation of the institution many victims of motor accidents on the Kingston by pass road came under his care

CORRESPONDENCE

IN MEMORY OF JOHN BLAND-SUTTON

To the Editor of THE LANCET

SIR,—I desire to add my tribute to the memory of the great surgeon and remarkable man who has just passed away My memories of Sir John Bland Sutton extend back to 1891 when I entered the Middlesex Hospital medical school Mr Sutton, as he was then called, was the junior assistant surgeon and senior demonstrator of anatomy He was a small, pale man with a dark moustache Amongst us younger students he was chiefly known as a brilliant teacher of anatomy, but there was talk too of remarkable operative dexterity and courage Our medical education had not then proceeded far enough to appreciate or even to know about the wealth of anatomical and pathological work which he had already accomplished In those days a junior assistant surgeon had very little opportunity to distinguish himself in the operating theatre except during the holiday months, and it was not until he was appointed surgeon to Chelsea Hospital for Women in 1895 that Sutton got his chance

It was on his advice that in 1898 I went to Chelsea as resident officer and by that time he was the ' star turn " there The surgical treatment of uterine fibroids was then in process of development against considerable opposition from certain quarters Assisted by the late Arthur Giles, Sutton operated every Monday afternoon and the theatre was crowded with surgeons from all parts of the world He had a remarkable power of infusing enthusiasm into those who served under him and all of us worked with a will to make the operations go off as perfectly as possible It was the beginning of that "team work" which is now an established practice in all first class surgical centres In the face of his brilliant dexterity and successful results the opposition to the surgical treatment of fibroids rapidly died down and to him more than to any other surgeon in this country is due the credit of changing professional opinion in the matter of these tumours But he did more than this for he raised the status of abdomino pelvic surgery out of the narrow rut of specialism in which it threatened to stick and created the gynæcological surgeon in place of the gynæcologist

In appraising his place as a great operator it is necessary to have regard to the state of surgery at the time when he entered the calling The new territory which Lister s discovery had opened to surgeons was being cautiously explored, antisepsis was still in the carbolic spray stage, steam sterilisation was unknown catgut was unsafe, silk, silkworm gut and silver wire were the popular ligature materials, the most advanced surgical attire was a carbolised mackintosh apron over ordinary clothes and the idea of rubber gloves was nearly 20 years distant Operating theatres were poorly equipped and a large proportion of surgical operations was carried out in the houses of the patients under very disadvantageous conditions There was no system and very little coördination As a result, surgery with very few exceptions was laborious slow and timid Bland Sutton perceived that for operative work to be reasonably safe under such conditions simplicity and speed were essential and his results justified his opinion He reduced the number of instruments he used to the very minimum six pairs of Spencer Wells forceps, a dissecting forceps a pair of scissors a scalpel, half a dozen needles and a couple of reels of silk thread sufficing him for any operation He used antiseptic solutions very sparingly, especially on his own hands, maintaining, much in advance of his time that they merely made the skin rough and more prone to harbour infection There can be no doubt that at the outset of his career his views and practice as regards operating were largely influenced by Lawson Tait, of whom he always spoke with great respect He was exceedingly quick and dexterous, yet light handed as well, and his determinations were taken with unfailing rapidity and carried out with unfaltering resolution To the last day of his surgical life tedious prolonged operations had no interest for him, and indeed he never entered upon them

Only those old enough to know, or being too young can yet visualise the operating theatre of the eighties can appreciate how much our Art is indebted to him Since this present century began surgery has undergone a profound and advantageous elaboration, purchased however by the loss to the surgeon of some of that self reliance which was so striking in Bland Sutton at the operating table The conditions under which surgeons now work mask this loss, but there are occasions still when the fate of the patient depends on this great quality alone and for that emergency every surgeon should keep within himself something of the spirit of Bland Sutton

I am, Sir, yours faithfully,

VICTOR BONNEY

Harley street W Dec 21st 1936

To the Editor of THE LANCET

SIR,—Bland Sutton was one of the few truly great men of the present century, he had innumerable interests outside his profession—travel, archæology, the drama, biology, &c Everyone of course knows of his work on comparative anatomy, but he was also an excellent botanist, particularly interested in orchids and other plants whose life history is associated with insect life He was, moreover, kindness itself to all those with whom he came in contact, and was especially good to the younger men Soon after I was qualified he asked me to prepare sections of all the interesting tumours which he removed or which were sent to him, and for ten years we met about once a fortnight to examine these microscopically I used to look forward to these meetings because he would always think aloud while looking down the microscope, and recount in his own amusing way the chief points in the clinical history He had a great power of carrying on the ordinary concerns of life while he was pondering something deeper and more important It was because of this that his output of work was so enormous although it was his custom to leave nothing not even the most unimportant detail, to others Although I must have received hundreds (perhaps thousands) of letters from him, I never received one that was not written, and the envelope directed, by his own hand His letters were always exactly to the point not a word too little and not a word too much

But his true character may perhaps be best exemplified by an incident which occurred in my out patient department a few years ago A nun came to consult me and I asked her if she had been in in patient in the hospital before 'Yes, she said, I was under Saint John ' I replied, ' you must surely mean Sir John. Yes' she said I do and she hastened to add but I could not have been more kindly treated had it been the saint himself

I am Sir yours faithfully

Dec 22nd 1936 SOMERVILLE HASTINGS

To the Editor of THE LANCET

SIR,—I have reason to be grateful to Sir John Bland Sutton not only for his stimulating friendship over a long period of years but for his help in other ways It was in my undergraduate days that Frederick Page told me about Bland Sutton and recommended me to get his book on tumours I had then read his little book on ligaments which had opened up to us students a new world in anatomy The book on tumours was at once arresting and fascinating and I never read a story with greater avidity Bland Sutton kept up a correspondence with Page about the treatment of the placenta in advanced cases of ectopic gestation and I remember the glee with which we looked forward to hearing what he had to say in this mild controversy With the arrival of the *Clinical Journal* on Friday nights there was the eager anticipation of finding something from his facile pen I shall never forget the warm reception he gave me when I first came to look round London in 1900 He invited me to see his work at Chelsea and to accompany him there in a victoria with a pair of beautiful greys His conversation was like his writings except for the quips difficult to reproduce in writing which always conveyed some lesson His London accent of which I think he was a little proud seemed to heighten the point of his remarks He told me he had been born within the sound of Bow Bells adding Thank God within easy reach of the green fields and the country

Bland Sutton's reverence for John Hunter was remarkable. I was once able to purchase three of Hunter's letters and thinking that one of them would be of interest to him I sent him a transcript By return came a characteristic note in his clear legible hand telling me how much obliged he was for the chance of becoming familiar with the letter and adding When you come to town be sure to bring it and show it to me but *don't trust it to the post.* Later I saw a good deal of his work at the Middlesex and each time there was something which impressed the visit on my mind His technique as has been said perhaps lacked finesse and in the early days of the rubber gloves he treated them with a certain amount of levity but he was skilful and adept in emergency and his results were remarkable In other people's difficulties too he was a never failing source of help but his precision made his communications short. When the husband of an old patient wrote him a seven page letter describing the symptoms from which his wife suffered and awaited in eager anticipation an equally lengthy reply soon it came but to this effect Dear Mr —— I am quite sure an operation ought to be performed Yours sincerely —— But it was enough That night I reopened the abdomen an uncertain illness was cleared up and recovery followed His memory was remarkable and although it astonished others he seemed to look upon it himself as the most ordinary thing

I am Sir, yours faithfully

HOSPITAL AMALGAMATION IN LIVERPOOL

To the Editor of THE LANCET

SIR —The Bill to amalgamate the four Liverpool general hospitals in accordance with the report of the Liverpool Hospitals Commission to which reference was made in an annotation on Dec 19th (p 1474) follows closely the provisions of the Birmingham United Hospitals Act 1934 There are however several interesting differences in detail. In the Birmingham Act the distinction between the members of the honorary medical and surgical staffs and the resident medical officers was not so clear as in the Liverpool Bill. The Birmingham Act authorised accommodation to be provided for private patients in accordance with a scheme approved by the Charity Commissioners The Liverpool Bill does not contain any reference to the Private Patients Act of last session and apparently its use will not be necessary especially as there is a clause authorising any members of the honorary medical and surgical staffs of the Hospital to charge fees to paying patients to the Hospital This raises the question whether the Liverpool United Hospital will have power to continue the present practice of allocating a percentage of the receipts from the Merseyside Hospitals Council to staff funds It would seem to be desirable to place the matter beyond doubt by the inclusion of some reference such as that contained in the Prince of Wales's Hospital Plymouth Act.

The governing body at Liverpool will consist of fifty-one members as in Birmingham with the difference that there will be two persons appointed by the University of Liverpool instead of only the dean of the faculty of medicine and two appointed by Merseyside Hospitals Council instead of three appointed by the two corresponding organisations in Birmingham

The Liverpool Bill contains provisions in reference to the honorary staffs which are not contained in the Birmingham Act Vacancies are to be filled by a committee consisting of the members of the Associated Voluntary Hospitals Board other than any medical or surgical members whom the said Board may by resolution exclude together with such medical or surgical members as the said Board may by resolution co-opt and four persons two of whom shall be laymen and two of whom shall be members of the honorary medical or surgical staff of the Hospital appointed by the general committee A layman appointed by the general committee shall be entitled to preside and if necessary to give a casting vote It seems to be an omission in the Bill that it makes no reference to the constitution of the Voluntary Hospitals Board The Bill also gives a definite constitution to the medical board which consists of the honorary medical and surgical staffs and one person two persons and four persons respectively appointed by the dental surgeons pathologists and anæsthetists There is no provision for the representation of any other section of the medical staff such as obstetricians and gynæcologists or radiologists to whom it may hereafter be thought desirable to give separate recognition though there is a power to coöpt within limits of particular offices set forth in a schedule The medical board will have its own chairman and secretary

No rule regulation or recommendation of the medical board shall have any force until the minutes of the meeting recording the same shall have been read to and confirmed by the general committee The medical board shall have the supervision of the medical and surgical work of the Hospital and all matters relating to the purchase of surgical instruments and apparatus shall be referred to the medical board but that board shall not have power to purchase any instruments or apparatus without the previous sanction of the general committee" The medical board will have twelve representatives on the general committee

The extent to which the provisions of the Birmingham Act have been followed in the Liverpool Bill shows that important precedents are being created so that the additional provisions relating to the medical staff incorporated in the latter deserve general attention, especially in places where the conditions are likely to render necessary similar legislation within the not distant future

I am, Sir, yours faithfully,

C E A BEDWELL

King s College Hospital, S E Dec 20th, 1936

CARDIOVASCULAR EFFECTS OF BENZEDRINE

To the Editor of THE LANCET

SIR,—In a very interesting article in THE LANCET of Dec 12th, 1936, Drs Anderson and Scott describe cardiovascular effects induced by benzedrine in six patients out of a series of twenty The patients selected were mild neurotics and psychotics, and it is stated a certain number of normal subjects were also investigated It would be interesting to know what proportion of the series were normals, and if any of the normal individuals complained of pain in the chest palpitations, or faintness Case No 6 had severe collapse eleven hours after the administration of 30 mg of benzedrine It is stated that an examination showed a 1–4 heart-block with an occasional extrasystole Although nothing abnormal was detected in the cardiovascular system before the experiment, it would be interesting to know the result of an electrocardiogram taken after recovery from the attack, to see if any organic lesion of the heart was demonstrated

The effect of benzedrine on normal persons has been investigated at this hospital on members of the resident medical staff The series included eight individuals On the first occasion four of them were given 30 mg of benzedrine by mouth and on a subsequent occasion the other four had 40 mg each by mouth The results after taking 40 mg were little different from those seen after taking 30 mg Blood pressure and pulse rate readings were made every half hour sitting down All cases showed a rise of blood pressure, which reached its maximum in 1½–2 hours and had returned to normal after 4 hours The systolic pressure rose from 20 to 30 mm and the diastolic from 10 to 20 mm The pulse rate in the majority of cases showed a slight increase after ½ hour, but later was slowed in all individuals, and was slowest 1½–2 hours afterwards when the blood pressure was highest

Although the rate was slow while sitting down it was very unstable, and the slightest exertion, such as getting up and walking around, caused great increase in rate The first subjective symptom noted was a slight feeling of the head not being quite clear Flushing of the face was experienced by some, and dryness of the mouth coming on after about one hour by nearly all The only unpleasant feelings noted were by two individuals who on standing up had a transient feeling of faintness In both the pulse rate had suddenly increased to about 130 On sitting down the feeling quickly passed off and the pulse rate in about ten minutes became again slower than normal

The euphoria was well marked in all and after 1½ hours conversation was at a maximum Many interesting and remarkable stories were told, mostly reminiscences of the past All wished to talk and none to listen The drug was taken at 8 P M, and its effect on sleep was well demonstrated The amount of sleep varied from 2–3 hours to none at all.

I am, Sir, yours faithfully,

J H FISHER,

Medical Registrar, General Hospital

Dec 22nd 1936 Southend on-Sea

MORTGAGED PRACTICES

To the Editor of THE LANCET

SIR,—The letter from Mr Carmichael in your issue of Dec 19th, 1936, does not appear to us to be more than a statement that the scheme offered by his finance company is the cheapest and least onerous available to doctors, no matter what the circumstances of the particular applicant may be, or whether he requires the whole or only a part of the purchase price Such an assertion, however, does not necessarily make it true in fact We have been closely into all the various schemes in force and would make no such sweeping statement about any of them. The value given for money is often as important as, or more important than, the exact price paid, the cheapest is not always the best

Plenty of doctors would rather not pay a gross rate of 6½ per cent (with a return of the income tax on the interest at the end of the year and a promise of a rebate of 1 per cent in certain circumstances) when the loan can be secured elsewhere at a net rate of 3½ per cent Plenty of doctors again might prefer a life policy which can be continued after the loan is repaid to one which provides decreasing cover and ceases when the loan is repaid, with the possible risk that health may prevent the doctor from securing life assurance which he is almost certain to need. There are many points which need considering, and true and impartial advice will seldom, if ever, take the form of recommending exactly the same scheme for everybody, no matter what his particular circumstances may be

We are, Sir, yours faithfully,

Birmingham Dec 24th 1936 LEE AND MARTIN LTD

THE FUTURE OF TEETH

To the Editor of THE LANCET

SIR,—Sir Norman Bennett's paper at the recent Public Health Congress is mainly an expose of present conditions and a plea for the intensification of efforts to deal with a deplorable state of affairs But there is no hope that way The dental profession is trying to push back the ocean with a mop, and until the (political) engineer builds a good tariff wall against sugar and white flour, I fear that the blood and tears of children will continue to flow needlessly in our clinics

Nearly 40 years' experience makes me think that dental disease is being neither treated nor prevented in the real meaning of those terms For those who are in earnest about it my experience would suggest the following action Abolish the beet-sugar subsidy and tax sugar like whisky, until sweets and toothache, like spirits and cirrhosis, become the luxuries of the rich Prohibit the importation of white flour and start an unceasing propaganda for well baked wholemeal bread having a legal maximum of water

This by way of a start only. In five years' time we should know enough to look for other causes—if necessary. There is hope in these proposals but none whatever in the present futilities.

I am, Sir, yours faithfully,

Sheffield, 1, Dec. 23rd, 1936. H. J. MORRIS.

DEARER DRUGS

To the Editor of THE LANCET

SIR,—In his recent annual report the chief medical officer to the Ministry of Health commented upon the cost of medicines prescribed for insured persons, which in England worked out at 1*d.* per head more than in the previous year. Sir Arthur MacNalty inferred that the average expenditure per head for the country—namely, 3*s.* 1*d.*—was excessive. I do not think this inference is a fair one. Anyone who is in touch with the drug market will have noted the steady rise in the wholesale prices of drugs, particularly essential oils and other drugs of vegetable origin, which has been going on for a long time past and seems likely to continue. The cost of many commonly prescribed drugs is now far ahead of what used to be considered their normal value. This rise in drug prices is due to various causes, among them the Italo-Abyssinian war, the civil war in Spain, the prolonged drought in the United States, and the steady increase in the demand for vegetable drugs in most parts of the world, especially the United States of America. Let me mention a few drugs out of many which are now much dearer than they were—gentian root, ipecacuanha, ginger, rhubarb, euonymus bark, aloes, hydrastis, buchu leaves; while others such as saffron, ergot of rye, orris root, squill and gum tragacanth have been valued during the past year at figures from twice to six times as high as those of a year or two ago. Among essential oils eucalyptus, star aniseed, clove, and lemon are much dearer than they were and the upward tendency continues. It seems likely too that the wide range of drugs grown in European countries and including such important articles as belladonna, henbane, aconite, and liquorice will continue to advance in price, partly owing to the policy of wholesale druggists in the U.S.A. in laying up larger reserves of European drugs as a precautionary measure in the event of supplies being cut off by war.

In view of these facts it seems clear that if the National Health Insurance drug bill is to be reduced drastic economies in prescribing will have to be practised to a degree which it is possible Sir Arthur MacNalty did not anticipate.

I am, Sir, yours faithfully,

London, Dec. 28th, 1936. F. C. GOODALL.

STANDARD OF ARMY RECRUITS

To the Editor of THE LANCET

SIR,—Your issue of Dec. 19th, 1936, records under Parliamentary Intelligence an account of a speech made in the House of Commons by Sir Arnold Wilson. He is there reported as criticising the rigidity of the medical examination of army recruits and as suggesting a civil inquiry into the working of the present system. I take this speech as an excuse for mentioning a problem which faces me, and I believe other civilian practitioners, from time to time, but not only in relation to the Army.

One is consulted by a patient who has applied to join the Army or some other branch of the Government or local service and who has been informed that his application must be refused unless he has an operation performed for an entirely symptomless varicocele. To perform an operation which the patient does not desire and which at the same time one would not conscientiously advise as being necessary for his health is a most humiliating professional experience; yet to refuse the operation is to debar the patient from joining the service for which he is applying.

My own experience and that of my colleagues whom I have consulted on this point is that a varicocele is a harmless anatomical condition; the text-books support this view. Are there any case records published of atrophy of the testis following a varicocele on which no operation has been performed? Is there any evidence that a condition harmless to a civilian citizen becomes pathological when he joins a police force? Is rejection of an applicant for Government or local service on account of a varicocele based on observation or on tradition?

I am, Sir, yours faithfully,

CECIL FLEMMING.

Upper Wimpole-street, W., Dec. 28th, 1936.

THE DISTRICT NURSE

To the Editor of THE LANCET

SIR,—In your leading article last week on district nursing you say that "it is likely that the Midwives Act of 1936 will further help the midwifery work undertaken by the Institute." As far as I can see the Act as administered by some of the local authorities is going to do a great deal of harm. In some places it almost seems that the county councils are so afraid that perchance general nursing may reap some advantage through the grants for midwifery that they are asking county nursing associations to enlarge their boundaries to such an extent that the midwife will spend most of her time travelling. The midwife's work is based on the number of births a midwife can attend, without due regard to the distances to be covered in sparsely inhabited districts or the nature of the country. Nursing associations were promised help for transport, but in one county at least where a transport grant is given the midwifery grant is so much the less. The reason given for this was that if a car was used more fees would be obtainable. If the transport grant is to be £25 towards the cost of running a car and the grant is to be docked of £25 in a mountainous country where there are few people and fewer births, where are the extra fees to come from to make up £25? Where in the past there has been a struggling district association in existence, supported by voluntary effort and always on the verge of bankruptcy, the powers that be may assess the district at a quarter of a midwife. The association will then get even smaller grants than formerly and will be obliged to raise their nurse's salary and pay for a pension scheme, uniform allowance, and telephones. What the local associations are asking their county offices is: How is it to be done? On making representations to our local authority we are told that they would prefer to take over the whole service themselves. Then what is to happen to the general cases, the pneumonias, the old people, and the dying? Surely these also matter as well as the babies? But there is not enough work or money to run a general nurse as well as a midwife in most rural districts.

I am, Sir, yours faithfully,

HON. SEC. OF A COUNTY NURSING ASSOCIATION.

Dec. 28th, 1936.

GRAINS AND SCRUPLES

To the Editor of THE LANCET

SIR,—Allow a reader of THE LANCET for sixty years a few words in appreciation of the series entitled Grains and Scruples The articles have almost without exception given me great pleasure and if here and there I am moved to criticism I can take this step freely since if I tread on any toes, at present at any rate, I cannot know on whose toes I am treading Anonymity gives the opportunity for criticism which some well known name might prevent

I was prepared to find that the consulting physician and surgeon and the specialist, generally practised writers, could certainly inform and probably entertain me That other types of medical man could do so equally has come as a revelation None of the writers has, I think, surpassed the country practitioner in the quality of his contribution, though personally I have found "A Chronicler" the most interesting, and he has set me wondering about the changing relationship of our medical press to the lay newspapers The latter busy themselves a good deal to day, as "A Chronicler" points out, with medical subjects To what extent, if any, are medical papers likely to retaliate ? Is there any chance that, seeing the intense interest which medical news appears to have for the non medical reader, medical papers will seek an increased circulation by making their columns more easily understood by those who have had no medical training ? Already a certain, though probably quite a small, proportion of these people do actually look at *The Lancet*, or *British Medical Journal*, or both every week At clubs many may be observed scanning their pages, and later they button hole any fellow member who chances to be a medical man and seek explanation As a matter of fact these readers do not find much that they cannot understand without help

There is a notable decrease in the publication of articles with a medical name attached which a year or two ago flooded certain daily newspapers A violent effort had been made from certain quarters to over throw the commonly accepted attitude of our profession regarding publication in lay papers over the writer's name The effort has failed—and a good thing too Sir, I wax garrulous as an old man will, and I must bring my letter to an end by saying I look forward to reading many more of the series Grains and Scruples —I am, Sir, yours faithfully,

Dec 24th 1936 SENEX

OBITUARY

ALFRED GREENWOOD, M D , B Sc Manch , D P H

Dr Alfred Greenwood, who died at Maidstone on Dec 4th, had not long retired from his position as chief health officer for the county of Kent Born at Sheffield in 1873, the son of the Rev E Greenwood, he was brought up at Southport, educated at the Wakefield Grammar School and Owen's College, Manchester, qualifying in medicine at Victoria University and taking the triple Scottish qualification, both in the same year, 1895 After qualifying he held a remarkable series of resident posts in or near Manchester, including surgical, medical, and poor law experience as well as residence in a famous children's hospital Five years after qualifying he entered the public health service, first at Blackburn and then at Crewe, until in 1913 he was appointed to the county of Kent when the late W T Howarth was transferred from Kent to the City of London Dr Greenwood was also school medical officer and chief tuberculosis officer He organised the county schemes for the prevention and treatment of venereal diseases, for maternity and child welfare, and the treatment of crippled children and completed the arrangements for tuberculosis started by his predecessor He was successful in correlating the voluntary work in the hopfields and in supervising the hopper encampments In the summer he arranged a very popular post certificate course for the midwives practising in the county He was keenly interested in cancer research serving on the council of the British Empire Cancer Campaign and acting for a time as chairman of its local executive In 1925 he was one of two representatives nominated by the Ministry of Health to visit Jugoslavia in order to study public health on behalf of the Health Section of the League of Nations Dr Greenwood held rank as Lieut Colonel R A M C (T F) He was mobilised on the outbreak of war in 1914 serving in succession as divisional sanitary officer sanitary officer of the Second Army central force and sanitary officer of the Southern Army He will be remembered as a conscientious public servant with a real talent for detail

PERCY A E RICHARDS, F I C , F C S

THE death occurred on Dec 22nd of Percy Andrew Ellis Richards, a well known analytical chemist, and past president of the Society of Public Analysts. Born in London in 1868, son of Robert Phelps Richards, he was educated at St Paul's School and King's College, London, and later studied chemistry under the late Prof Heaton, with whom he worked, in particular as an assistant at the Charing Cross Hospital There his colleague and contemporary was the late Archibald Vasey, for many years superintendent of THE LANCET laboratory when the analyses of foodstuffs and pharmaceutical preparations, for which we made ourselves responsible, were done on the premises Richards succeeded Heaton in his post at Charing Cross Hospital, where he lectured on pharmacy and analytical chemistry in the medical school As a result he published a guide to the examination in practical chemistry of the English Conjoint Board, in which a well prepared and accurate system of procedure was laid down for the guidance of the students in making ordinary chemical preparations He was appointed public analyst to the parish of St Martin in the Fields, and shortly afterwards to the same post for the borough of Hammersmith and lastly for the City of Westminster He was a member of the council and examiner at the Institute of Chemistry, and as the outcome of much teaching experience he wrote a work on practical chemistry of a larger scope than his previous treatise But he made no attempt here to go beyond the limit of the examinations in preliminary subjects at the University of London, and the book was a sound introduction to elementary methods of qualitative and quantitative analysis He contributed frequently to medical literature, as well as to the *Chemical News* and the *Analyst* while his connexion with Vasey led often to joint work being conducted in THE LANCET laboratory the outcome being the publication in these columns of pharmaceutical notes

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations Each contributor is responsible for the section for a month his name can be seen later in the half yearly index

FROM A PUBLIC HEALTH CLINICIAN

I

Of all hobbies natural history best befits the training and daily life of a doctor And of all branches of natural history ornithology is the best suited Observation in this field must be swift and accurate; with use it becomes more detailed And there is nothing more helpful to our daily work than the power of swift accurate and detailed observation It is not enough to note the passage of a large or small bird with bright or sombre plumage we must note the details of the colouring the colour of wings legs and rump There are also other points such as the manner of perching and the mode of flight or the habits of feeding The habits and idiosyncrasies even of common species provide a constant field of changing interest and training It is not only the eye that is trained but equally the ear The recognition of special notes and songs makes the whole countryside seem more friendly and however long we may have been watching or listening each day may produce some new sound or display some unfamiliar feature

* * *

The drawback to a prolonged study of ornithology is the limited number of British birds so that, after a few years the thrills of new discoveries become fewer but there is always the excitement of seeing some new antic and it is here that other branches of natural history may fill the gaps The observer may turn to entomology or to the more leisurely contemplation of botanical mycological or bryological finds Fortunately no doctor who has to earn a living will ever become a really expert ornithologist or indeed expert in any branch of natural history he must remain a dilettante naturalist The more dilettante the student the more relaxation is he likely to achieve; discoveries which to the expert would be mere dross are to him golden A lifetime can be spent learning in this domain and much will still remain undisclosed or undiscovered Medicine in the broadest sense is similar for forty years we may continue observing and note taking yet the very next day we may detect a clinical entity or a syndrome which we have never before noticed read about or even heard tell of

* * *

Accuracy of observation by ear or eye is a comparatively rare gift and experience of the examination of girl guides and boy scouts tends to confirm this impression How often one reads in their reports that the birds sang sweetly or that the observer saw several beautiful birds how seldom is an attempt made to describe correctly the sounds heard or to give the exact plumage of any one bird even of a robin or house sparrow Small blame to the scouts for they are novates and we doctors are trained observers yet when stories of cases are narrated to us by colleagues we hear of influenza rheumatism or neuritis when what would interest us more would be the exact symptoms of which the patient complained in chronological order and in plain English

Plain English of course may have its limitations and taste in the selection of words is a little uncertain One doctor always employs the word belly when speaking or writing of what we usually call the abdomen She had a pain in the belly says he or perhaps Two days later I opened the belly or again when questioning a patient he may ask have you had any pain or discomfort in the belly ? He does it so nicely and with such a gentle and cultured air that I am almost persuaded that the word should be more freely used and that it is more apt when speaking to a patient than stomach or tummy ; but there prejudice whether inborn or acquired steps in I fall and find myself preferring instinctively abdomen or stomach

* * *

Those who manufacture chemicals and other articles of commerce deluge us with samples of their wares and it is difficult to decide how best to utilise or dispose of these Put them in a cupboard to await an appropriate patient there they are discovered dusty desiccated or mildewed some twenty years later; dispense them to a patient and the result may be disappointing or on the other hand more and more may be asked for our samples become exhausted and we have to buy further supplies at exorbitant prices of something in which we perhaps have little faith If we decide to take them ourselves we may have to wait long for the right illness; or a false parsimony may induce us to take them without delay and so maybe spoil the digestion of an otherwise enjoyable dinner

* * *

It is fortunate that I have made the acquaintance of a Scottish spinster of uncertain age who enjoys swallowing any and every sample that I am prepared to hand over *Lactic acid bacilli* in legion have found their way to her and scores of aperients dispensed as liquid pills or powder Tonics too please her and many familiar green bottles have passed that way as well as cough syrups and the like Highly or less highly concentrated hormones and vitamins delight her be they from corn husk testis ovary or pituitary But best of all did she like a small yellow bottle of concentrated vitamins or hormones and so great was her affection for this tonic that she wished to obtain it privately The chemist offered to supply it at 10*s* 6*d* a bottle this did not please her I wrote the firm and they would let me have it at a professional price of 6*s* 6*d* that still did not appeal to her Then I read the bottle and noticed that the specimen contained 20 per cent of alcohol and explained to her that it was that ingredient perhaps, which made the remedy agreeable If she spent her money I suggested on cooking sherry or even upon beer her outlay would be better repaid I cannot yet say whether my advice was taken

Fortunately some years have passed since we ceased to receive packets of handkerchiefs or fountain pens for purchase or return Handkerchiefs were bought and the price was not unreasonable but a fountain pen I once retained without payment to see what happened After a series of letters which remained unanswered the pen stayed with me to be rediscovered many years later I could not make it serve the purpose which its designer had intended, and so after all it died unused Perhaps similar pens shared a similar fate, and so this method of salesmanship became unprofitable

* * *

Students are led to believe that the general practitioner is a dangerous necessity, seldom other than ignorant and incompetent In practice later, on the other hand, we are told, when consultants address us, that we are the backbone of the profession, up to date, eager, wise, and conscientious It would be serious for our moral welfare if we did not encounter occasional fractious patients who frankly criticise our methods Most of us would acknowledge on reflection that the majority of doctors of consultant rank are more intelligent and better informed than the majority of general practitioners The chief mental difficulty of the general practitioner is isolation He is conversing with and treating those who know nothing about medicine and who accept his dicta and explanations almost without question Gradually the isolated doctor, and in this respect he may be as much isolated in town as country, becomes to believe fervently in himself and in his own dicta, and observation of one or two lucky cases may lead him to believe that his therapeutic methods are superior to those of others The conceit occasionally revealed by such doctors is surprising, yet such a doctor may not be useless to the community A man who believes sincerely in his own powers and his own remedies will have a better and more useful influence over his patients than one who is diffident and hesitant

* * *

The remedy for isolation is within reach of everyone, it is to attend meetings, encounter others, and exchange views These opportunities are provided by local medical societies and the B M A But there will always be a large number who never attend meetings and who deteriorate unconsciously but continuously The best doctors in any locality are those who attend meetings The most dangerous period is the beginning, once the habit of meetings and post-graduate study is formed all goes well, but these habits should be cultivated in the first year of practice or it may be too late

* * *

It is curious how often doctors continue to believe in, and to practise, methods which were foremost in their student days but which have now been largely abandoned It is almost possible to date a man by his methods There will be the vaccine fan turned out in the opsonin days, the country surgeon of a little later date who fixes the abdominal viscera, the man who circumcises all the babies, or blocks up sinuses with gauze, or the one who has one or other special drug for curing pneumonia Yet all these happenings increase the varied interest which medical practice and life provide

PARLIAMENTARY INTELLIGENCE

INSANITY AND DIVORCE

BEFORE the House of Commons rose the Marriage Bill was further considered by Standing Committee A, when Lieut Commander AGNEW moved an amendment to delete the paragraph which provides that incurable insanity after the respondent has been certified a lunatic for at least five years shall form a ground for divorce He said that the proposals of the promoters of the Bill differed very widely from the recommendations of the majority report of the Royal Commission of 1912 The Mental Deficiency Act of 1930 might have altered the situation, but through the majority report very great power resided in the Lunacy Commissioners He regarded the proposals of the Bill as a weakening of that position, and the essential safeguards which the Commission sought to recommend would be entirely lacking Before a petitioner could go to the court under the five-years rule and sue for a divorce, the spouse might leave the mental hospital from time to time and there was nothing in the Bill to stop what they all wanted to avoid, the the procreation of children who themselves might be mentally afflicted This social evil would therefore go on exactly as before Were those that might subsequently recover their sanity to come out and find that a new marriage had been contracted? The very knowledge that this might occur would have a detrimental effect on their recovery while they were in the asylum. He thought it would be wiser to keep the insanity in the same position as total bodily paralysis or epilepsy grave calamities that deprived one partner of all that marriage meant —Mr HERBERT who was in charge of the Bill, replied that the promoters of the Bill intended that proceedings should be served on the King's Proctor, who should refer to the Board of Control They were now inserting a new ground for divorce and the present feeling was that the subsidiary effects and results could be dealt with under Rules of Court which had to be laid before Parliament so that control would be effective

Sir ARNOLD WILSON, who opposed the amendment, said that there were something like 50,000 married persons of unsound mind who were now in institutions in this country and the majority had been there for more than five years Since the Royal Commission sat in 1912 one of the aspects of insanity that had been best established was that as a rule it was not a catastrophic accident comparatively late in life, it was more often inherent, usually coming out long after the marriage took place There was not much ground for believing that there had been any very serious eugenic consequences from the liberation of persons during temporary periods of sanity

Mr LYONS asked why they should take only one kind of disease—disease of the mind—and use that as a ground of divorce? The proposal required the very gravest scrutiny He believed that public opinion was in favour of maintaining the obligation of the marriage tie and not of whittling it away at the will of some new statute designer Such experiments were fraught with danger —Mr RAIKES said that if there were to be any extended grounds for divorce at all insanity had a stronger case than anything else There were thousands of people who had been driven by the present laws into irregular unions

Mr G GRIFFITHS said that there had been more working-class married women pronounced insane since 1926 than ever before That was because of the domestic difficulties from not having the money to carry on the home If a working man's wife was sent to an institution this Bill might be taken advantage of to obtain a divorce after she had been there 5 years She might come out completely cured and find that her husband had remarried. He suggested that the period should be increased from 5 to 10 years

This amendment was defeated by 16 votes to 5

Sir A. WILSON moved an amendment, first, to substitute for the word "insane" the words "of unsound mind" in order to bring the Bill into line with the wording of the Mental Treatment Act, 193

Secondly the amendment substituted for the words has been continuously a certified lunatic the words 'has been continuously under care and treatment' The former words were found to be too narrow because they excluded a criminal lunatic, but included members of the fighting forces who could in certain circumstances be detained without a statutory certification The Bill did not provide for the important cases of persons certified and detained in an institution under a reception order and kept as a voluntary patient after the expiration of the order That class included one in four of all the persons admitted into institutions last year They were none the less of unsound mind because they were admitted as voluntary patients and not under compulsory certification. From the point of view of administration and psychology it was of the greatest importance that they should not do anything to discourage voluntary patients The mere knowledge that under the Act of 1930 the voluntary patient had the right on giving notice to leave probably did more towards bringing about a cure if a cure could be effected, than any other single thing The word incurably remained and the Court would have to be satisfied by the highest medical authorities that the patient was in fact incurable.

This amendment was agreed to

UNEMPLOYMENT ASSISTANCE

Just before the recess Mr **GEORGE HALL** moved the suspension of the Unemployment Assistance (Determination of Need) Regulations in so far as they involved reductions in existing allowances. The Labour Party he said had not in any way withdrawn their hostility to the regulations as a whole and especially to the means test They wished the Government would consider the wider social and economic cost of the paralysed and wretched groups of communities now suffering in South Wales in the North and in Scotland and remember that they were a very heavy off-set to the seeming prosperity of the industrial Midlands, London, and the South Application of the new regulations would not only drive the unemployed still further into the depths of starvation, but would impose new cuts on the already low wages of the employed workers would further destroy family life, would so reduce the purchasing power of the people that small traders and shopkeepers would be driven into bankruptcy, and the already difficult task of the local authorities in those areas would be made impossible In Mountain Ash for instance between 40 and 45 per cent of the insured persons had been unemployed and 80 per cent of the men had come under the operation of the Unemployment Assistance Board In the whole of Glamorgan county they had discovered 0800 children between the ages of 5 and 14 who needed clothes and 13 000 who needed boots But in the memorandum issued by the Board it was stated that reductions in allowances would be necessary Within the next few months some 00 000 persons would suffer reductions.

Mr **BOOTHBY** said he did not believe the agitation in the country about nutrition was a mere stunt There was a tremendous lot behind it They had the authority of medical and scientific opinion which was beyond reproach that about 20 per cent of the population were under-nourished at the present time and if proof was required they found it in the figures of rejections for recruiting particularly in the West of Scotland Children and nursing mothers in the distressed areas were not at the present moment adequately nourished and the cost of that on the national disease bill was very great. He wondered how much of the £20 000 000 spent on disease alone in Scotland was due to the fact that in their childhood so many of the young men and women were under-nourished and badly fed There was no doubt that a blow was going to fall on some of the unemployed and mainly in the most distressed areas. The Government had been asked to introduce legislation to deal with this particular problem and the Chancellor of the Exchequer had promised to do so next May But in the very nature of things that must be long term legislation. Nothing effective could be done for the distressed areas for another year at least—it might be much longer The motion before the House asked that during that unstated period there should be no further penalties imposed. That was a reasonable request What was the point from the national point of view of reducing the purchasing power of the people in the distressed areas by a single penny?

THE LABOUR MINISTER'S REPLY

Mr **ERNEST BROWN** said that the new regulations came into force on Nov 16th and the process of reviewing cases was nearing completion Large numbers of persons had received notices that their allowances would be increased while no applicant had received a notice that his allowance would be decreased as a result of the new regulations These regulations, as the motion really admitted by implication were a considerable improvement on the old ones. Their effect would be to remove some of the inconsistencies of unequal treatment which obtained under the standstill arrangement On the basis of a review of 612 000 cases they had found that they were likely to have more than one-third of the cases receiving increases. Where reductions fell to be made because excess payments not needed were being made the reductions would be made gradually in order to avoid hardship If a man's earnings were less than 25s there would be no reduction from his standstill allowance If his earnings were between 25s and 60s there would be deducted only the amount by which his earnings exceeded twice the amount of his allowance He thought this was a fair rule The Board had told the advisory committees that all households in which more than half of the resources consisted of *some form of income other than earnings* should be excluded altogether as also would be households where the principal resources consisted of the earnings of sisters of the applicant or a married son, or of a more distant relative Applicants with earning brothers and sisters would be included only if their fathers were earning substantial wages The Board had suggested to the advisory committees that in the class of case to be affected the payment made should not exceed by more than 15s or 20s the amount of the applicant's needs as calculated on the new standard. The careful and detailed analysis laid before the House in July seemed to show that the hardships felt under the old regulations had been removed

The motion was negatived by 218 votes to 135

PIT-HEAD BATHS

In the House of Commons on Dec 10th, Mr **GALLACHER** moved:

> That this House in view of the advance that is taking place in housing in health and in hygiene is of opinion that pit head baths have become an urgent necessity for all mining communities and recognising the limited resources of the Miners Welfare Committee and its inability under present conditions to cope with the demand being made upon it expresses the opinion that the Department of Mines should immediately institute an inquiry on the best method of amplifying the finances at the disposal of the Committee and thereby ensure that pit head baths will be established as a recognised part of the equipment of the mines of this country

He said he appealed on behalf of the wives and mothers in miners' homes for the immediate installation of pit baths at every working pit in the country Though the various departments of the State were now doing a great deal to try to cope with infantile mortality and children's diseases they had very much further to go and here right before them there was a danger facing the children that they could immediately remove A young child might be affected by one of the epidemics common to children and the father was forced by the exigencies of the situation to carry into his home coal dust and gases his damp sodden clothes had to be hung up to dry The Royal Commission on Housing in Scotland referring to such conditions in miners' homes had said "The risk to the health of the children is very great" No time should be lost in saving the children from this menace But the miners themselves ought also to be protected They came up from the pits soaking, and then they had to travel home in their soaked clothes for miles It was an intolerable position in which to place any man From 1920 to 1926 only £121,463 had been allocated for baths out of a total of £4 500,000 The 1926 Act imposed upon the Central Committee the specific duty of providing pit head baths at all coal mines, as far as reasonably practicable, and required that the proceeds of the royalty levy should be used for that purpose The 1934 Act laid it down that a sum should be added to the fund that came from the royalty levy providing a total of £375 000 annually for installing baths That was the fund that the Welfare Committee now had at their disposal for baths The Committee, he believed, were working as energetically as possible within the limits of their means But the Committee originally had the whole of the funds, four-fifths going out to the districts and one-fifth being retained for general purposes connected with welfare Then £375 000 was taken away from the general fund for baths, which meant that the fund for welfare had become much less All the time the administrative expenses and the staff were increasing This situation brought all kinds of criticism against the Committee which they did not deserve He urged that the control of the installation of baths should be placed in charge of the Mines Department The Government should make an interest-free loan equivalent to 10 years' income of the fund

Mr **WATSON**, seconding the motion, said that where baths were provided they were told that 90 per cent of the men were willing and anxious to use them He hoped that the motion would be carried unanimously and that they would find the Government sympathetic

Mr **LEWIS JONES** moved the following amendment

> That this House while appreciating the great advantages to the mining community resulting from the provision of pit head baths is of opinion that the report of the Departmental Committee of Inquiry which resulted in special provision for the financing of pit head bath construction by the Mining Industry (Welfare Fund) Act 1934 provides the House with full and sufficient information on this important subject

He said that he appreciated the need for more baths, but he was satisfied that the Welfare Committee were making reasonable progress in providing them, and the district committees were showing increased interest in the movement The continued increase in output in 1935 and 1936 justified the expectation of substantial increases in the income of the Welfare Committee ' With the complete information available in the Departmental Committee's report, with the annual report of the Welfare Committee, and with the improved financial position of the coal industry generally he suggested that the work of the Welfare Committee should be allowed to proceed without further interruption —Mr **ROWLANDS** seconded the amendment He submitted that no case had been made out for demanding an inquiry on this question because all the information necessary was at the disposal of the Ministry at the present time

Captain **CROOKSHANK**, Secretary for Mines, said that he had no statutory responsibility for enforcing anything and the whole question of pit-head baths was one for the Welfare Committee to deal with and he was sure that they would appreciate what had been said in the House that afternoon It was not a shortage of money that was holding up any programmes The Committee had come to the conclusion that it would be possible to speed up to the extent of expenditure from £375 000 a year to the rate of £600 000 for each of the next two years In addition to 182 baths opened, 34 being built and 25 tendered for by the end of this year there would be by the end of 1938 about 10 further baths for which negotiations had already been started and some 55 negotiations for which had not been started, but of which the general idea had been adopted. This would bring the total by the end of 1938 up to 336 baths with accommodation for some 425,000 persons That envisaged considerable acceleration, and since the expenditure concerned ran into rather big figures, that was about the maximum speed possible, but it was not shortage of money that was holding up the programme

After further debate Mr **GALLACHER** asked if the Minister was prepared to give an undertaking that he would consult with the Welfare Committee and with them work out a scheme covering all the applications now before the Committee so that each of the pits would have some idea whether or when they were likely to have an installation

Captain **CROOKSHANK** replied that he was certainly prepared at all times to consult the Welfare Committee The amendment was withdrawn and the motion agreed to

DISTRESS IN THE HIGHLANDS AND ISLANDS OF SCOTLAND

Mr R **GIBSON** moved that the House should call upon the Government to formulate without delay proposals designed to arrest depopulation and poverty among the remaining inhabitants of the Highlands and Islands of Scotland and to provide them with facilities for earning a decent livelihood.

He said that the distress in these areas and the pressing need for remedial measures were keenly felt not only there but wherever descendents of Highlanders lived

After further debate Mr **ELLIOT**, Secretary of State for Scotland, replying to the debate said that great efforts had been made by the Central Government to deal with this problem. In 1935–36 over £1,500,000 had been paid to the Highlands and Islands by Government grants and there was a further £1,400,000 being spent on pensions and unemployment payments The Highlands and Islands medical service, which was a striking success, involved the expenditure of considerable sums and also the maintenance of a very much higher standard of medical service than the area could afford for itself. Though there were still considerable distances over which sick persons had to be brought, that those distances were being shortened each year, that the hospital services were being improved, and that new hospitals were being built Grants were now being approved of over £50,000 for additional general hospitals in Shetland, Lewis, and Orkney, and grants had been made to places like Inverness Infirmary to bring it up to the standard of a full general hospital After referring to the considerable grants made to the Highlands and Islands in respect of roads, education and housing, he said that when they spoke of distress and the danger of the collapse of the future welfare of a whole community they must be careful not to form an exaggerated view of the situation It would be a great disservice to the Highlands themselves if they did so It was well worth noting that the vital statistics of the Highlands were very much better than those of Scotland as a whole The adjusted death-rate in the Highlands was only about four fifths of that for Scotland. The sickness rate among the insured population was also less, being only 70 per cent of the whole country and the infant mortality was 32 per cent lower These were not the signs of a dying and decaying race, but of one that had undergone and was undergoing hardships and required that its lot should be improved, but they did no service to either the Highlands or to their inhabitants to depict them in a scheme of unrelieved blackness and gloom —Mr **JOHNSTON** What about the tuberculosis figures? Mr **ELLIOT** said he had not got those figures with him but the right hon. gentleman would know that the Highland population was susceptible to tuberculosis It was not so much in the Highlands themselves as when the inhabitants migrated to the crowded cities that the rate went up.

The motion was agreed to

PUBLIC HEALTH

THE HEALTH OF THE SCHOOL-CHILD

The annual report of the chief medical officer of the Board of Education is the product of the whole school medical service condensed and edited by the medical staff at Whitehall with Sir Arthur MacNalty as the final censor The school medical reports which go back to 1909 show the evolution of the school medical service although that of 1935 is obviously the successor of that of 1934 it is widely different in character from the reports of twenty or even ten years ago

ROUTINE INSPECTION

The most notable feature of the present report is Chapter III which though it bears the title of Routine Medical Inspection is really a reply to criticisms of the service made by Dr H L. Crouk Dr H Herd Dr G A. Auden and others and to a lively discussion at the R S I conference at Bournemouth It is unusual in an official report to find an apology for a government scheme against outside criticism but the constructive nature of the Bournemouth suggestions called for consideration and we much appreciate that this should be given them in the report of the chief medical officer It was not proposed at Bournemouth that periodical routine examinations should be abolished but that there should be greater liberty allowed to modify them by those school medical officers who are admittedly specialists in this sphere of medical work. The answer of the Board is that it sees no reason at present to modify the requirement of periodical inspections but the tone of the chapter in Sir Arthur MacNalty's report leaves the impression that the Board is prepared to modify the schedule if adequate argument is forthcoming for doing so It has been pointed out that though school medical officers of the experience of Drs. Auden and Herd might well be given freedom the majority of school medical officers are juniors who could not be expected to work an adaptable scheme of inspection without the schedule and precise instructions from headquarters. Apart from its insistence on the three periodical routine inspections the Board does allow wide latitude in the conduct of school medicine and following the practice of the Ministry of Health connives at much it does not actually sanction if it is convinced that it is of public benefit

NUTRITION

To the public and to doctors not specialising in school medicine the most interesting chapter of the report is that dealing with nutrition for 1935 was the first year in which the social research in feeding which has been such a prominent feature of the present decade could be put to practical test in the experiment of the milk in schools scheme Nutrition of school children is now assessed in four categories —excellent normal slightly subnormal and bad The groups are undefined and there is some but not much variation in individual ideas of what the headings mean but they are the least confusing available at present and leave open the field for experimental tests of nutrition Children are taller and heavier to-day than they were formerly This is a universal finding It is not necessarily all due to improved nutrition but there is no doubt that the nutrition of our children has improved for all the special tests used show an upward trend So far as we can see at present the milk in schools appears to do what was expected of it but has not done all that it can do from a misunderstanding for which the Board itself is partly but perhaps unavoidably responsible A considerable number of children for whom the milk is necessary fail to get it because they fall between those who can afford to pay for it and those who obtain it free A small group whose parents professed that they were unable to pay and who were not found subnormal by the doctor exists because the Board laid down restrictions on the supply of free milk. Some authorities relentlessly follow the Board's instructions, others practically ignore them generally they are lapsing for there is agreement amongst all political parties that there should be no risk of under nourishment of children which could be relieved by the supply of milk at the public expense Economically the provision is so cheap and malnutrition so dear that the restrictions cost more than the milk. Severe malnutrition is not common and what does exist is largely due to causes other than under nourishment but it is significant that percentages of bad nutrition are generally highest in the distressed areas Durham county showing much the worst count Of the boroughs and urban districts, Mountain Ash U D with 8 4 per cent and Jarrow with 6 7 per cent bad nutrition are notable exceptions to the average of less than 1 per cent. Numerous tests for nutrition are being tried out all of which are helpful but nutrition being a dynamic function can never be fully assessed by static measurements Like everything else in human biology chemistry and physics can give us evidence but it requires a physician to make a diagnosis

RESULTS

In the conclusion Sir Arthur MacNalty discusses the results of the school medical service which has been in operation for 27 years He asks What is the country getting in return for this expenditure? Has the enormous amount of money and time and intelligence given to this function produced an adequate return? The striking improvement in cleanliness and nutrition the growing rarity of the graver diseases such as tuberculosis, and the amount of treatment carried to a successful issue for minor diseases which formerly were neglected is some answer to this but for several reasons, statistically the results appear to be much less good than they are in fact. Some of the defects of children such as refractive errors and low intelligence are physiological deviations which can be relieved but not abolished so these show no drop in figures. In other matters our standard has steadily advanced Thus formerly ear disease meant otorrhœa with visual or olfactory evidence; to-day we have aural clinics to discover the commoner and less obvious disorders of the ear Running nose and the catarrhal conditions which go with it were hardly noticed at all in the early days of inspection; to day, though these are far less common than they were they are an important element in school work

The dental service is not yet fully developed There are about 5 000 000 children on the elementary school roll In 1935 3 360 818 of these were dentally inspected and 2,290 404 required treatment Treatment was provided for 1 474 083 but it is not to be presumed that they all received complete treatment However for the first year in the history to such conditions in miners' homes had said "The risk to the health of the children is very great" No time should be lost in saving the children from this menace But the miners themselves ought also to be protected They came up from the pits soaking, and then they had to travel home in their soaked clothes for miles It was an intolerable position in which to place any man From 1920 to 1926 only £121,463 had been allocated for baths out of a total of £4,500,000 The 1926 Act imposed upon the Central Committee the specific duty of providing pit-head baths at all coal mines, as far as reasonably practicable, and required that the proceeds of the royalty levy should be used for that purpose The 1934 Act laid it down that a sum should be added to the fund that came from the royalty levy providing a total of £375,000 annually for installing baths That was the fund that the Welfare Committee now had at their disposal for baths The Committee, he believed, were working as energetically as possible within the limits of their means But the Committee originally had the whole of the funds, four-fifths going out to the districts and one-fifth being retained for general purposes connected with welfare Then £375 000 was taken away from the general fund for baths which meant that the fund for welfare had become much less All the time the administrative expenses and the staff were increasing This situation brought all kinds of criticism against the Committee which they did not deserve He urged that the control of the installation of baths should be placed in charge of the Mines Department The Government should make an interest-free loan equivalent to 10 years' income of the fund.

Mr WATSON, seconding the motion, said that where baths were provided they were told that 90 per cent of the men were willing and anxious to use them He hoped that the motion would be carried unanimously and that they would find the Government sympathetic

Mr LEWIS JONES moved the following amendment

> That this House, while appreciating the great advantages to the mining community resulting from the provision of pit-head baths is of opinion that the report of the Departmental Committee of Inquiry which resulted in special provision for the financing of pit-head bath construction by the Mining Industry (Welfare Fund) Act 1934 provides the House with full and sufficient information on this important subject

He said that he appreciated the need for more baths, but he was satisfied that the Welfare Committee were making reasonable progress in providing them, and the district committees were showing increased interest in the movement The continued increase in output in 1935 and 1936 justified the expectation of substantial increases in the income of the Welfare Committee With the complete information available in the Departmental Committee's report with the annual report of the Welfare Committee, and with the improved financial position of the coal industry generally, he suggested that the work of the Welfare Committee should be allowed to proceed without further interruption —Mr ROWLANDS seconded the amendment He submitted that no case had been made out for demanding an inquiry on this question because all the information necessary was at the disposal of the Ministry at the present time

Captain CROOKSHANK, Secretary for Mines, said that he had no statutory responsibility for enforcing anything and the whole question of pit-head baths was one for the Welfare Committee to deal with, and he was sure that they would appreciate what had been said in the House that afternoon It was not a shortage of money that was holding up any programmes The Committee had come to the conclusion that it would be possible to speed up to the extent of expenditure from £375,000 a year to the rate of £600 000 for each of the next two years In addition to 182 baths opened 34 being built and 25 tendered for by the end of this year there would be by the end of 1938 about 40 further baths for which negotiations had already been started and some 55 negotiations for which had not been started, but of which the general idea had been adopted. This would bring the total by the end of 1938 up to 336 baths with accommodation for some 425,000 persons That envisaged considerable acceleration, and since the expenditure concerned ran into rather big figures, that was about the maximum speed possible, but it was not shortage of money that was holding up the programme

After further debate Mr GALLACHER asked if the Minister was prepared to give an undertaking that he would consult with the Welfare Committee and with them work out a scheme covering all the applications now before the Committee so that each of the pits would have some idea whether or when they were likely to have an installation

Captain CROOKSHANK replied that he was certainly prepared at all times to consult the Welfare Committee The amendment was withdrawn and the motion agreed to

DISTRESS IN THE HIGHLANDS AND ISLANDS OF SCOTLAND

Mr R GIBSON moved that the House should call upon the Government to formulate without delay proposals designed to arrest depopulation and poverty among the remaining inhabitants of the Highlands and Islands of Scotland and to provide them with facilities for earning a decent livelihood.

He said that the distress in these areas and the pressing need for remedial measures were keenly felt not only there but wherever descendents of Highlanders lived

After further debate Mr ELLIOT, Secretary of State for Scotland, replying to the debate said that great efforts had been made by the Central Government to deal with this problem. Apart from its insistence on the three periodical routine inspections the Board does allow wide latitude in the conduct of school medicine and following the practice of the Ministry of Health connives at much it does not actually sanction if it is convinced that it is of public benefit.

NUTRITION

To the public and to doctors not specialising in school medicine the most interesting chapter of the report is that dealing with nutrition for 1935 was the first year in which the social research in feeding which has been such a prominent feature of the present decade could be put to practical test in the experiment of the milk in schools scheme Nutrition of school-children is now assessed in four categories —excellent normal slightly subnormal and bad The groups are undefined and there is some but not much variation in individual ideas of what the headings mean; but they are the least confusing available at present and leave open the field for experimental tests of nutrition Children are taller and heavier to-day than they were formerly This is a universal finding It is not necessarily all due to improved nutrition but there is no doubt that the nutrition of our children has improved for all the special tests used show an upward trend. So far as we can see at present the milk in-schools appears to do what was expected of it, but has not done all that it can do from a misunderstanding for which the Board itself is partly but perhaps unavoidably responsible A considerable number of children for whom the milk is necessary fail to get it because they fall between those who can afford to pay for it and those who obtain it free A small group whose parents professed that they were unable to pay and who were not found subnormal by the doctor exists because the Board laid down restrictions on the supply of free milk. Some authorities relentlessly follow the Board's instructions others practically ignore them generally they are lapsing for there is agreement amongst all political parties that there should be no risk of under nourishment of children which could be relieved by the supply of milk at the public expense Economically the provision is so cheap and malnutrition so dear that the restrictions cost more than the milk Severe malnutrition is not common and what does exist is largely due to causes other than under nourishment but it is significant that percentages of bad nutrition are generally highest in the distressed areas, Durham county showing much the worst count Of the boroughs and urban districts, Mountain Ash U.D with 8 4 per cent. and Jarrow with 6 7 per cent bad nutrition are notable exceptions to the average of less than 1 per cent. Numerous tests for nutrition are being tried out, all of which are helpful, but nutrition being a dynamic function can never be fully assessed by static measurements. Like everything else in human biology chemistry and physics can give us evidence but it requires a physician to make a diagnosis

RESULTS

In the conclusion Sir Arthur MacNalty discusses the results of the school medical service which has been in operation for 27 years. He asks: What is the country getting in return for this expenditure? Has the enormous amount of money and time and intelligence given to this function produced an adequate return? The striking improvement in cleanliness and nutrition the growing rarity of the graver diseases, such as tuberculosis, and the amount of treatment carried to a successful issue for minor diseases which formerly were neglected, is some answer to this; but, for several reasons, statistically the results appear to be much less good than they are in fact Some of the defects of children such as refractive errors and low intelligence, are physiological deviations which can be relieved but not abolished so these show no drop in figures In other matters our standard has steadily advanced. Thus formerly ear disease meant otorrhœa with visual or olfactory evidence to-day we have aural clinics to discover the commoner and less obvious disorders of the ear Running nose and the catarrhal conditions which [illegible] with it were hardly noticed at all in the early days of inspection to-day though these are far [illegible] common than they were, they are an impor[illegible] element in school work.

The dental service is not yet fully [illegible] There are about 5,000 000 children on the [illegible] school roll. In 1935 3,368 818 of these [illegible] inspected and 2,290 404 required treatment [illegible] ment was provided for 1 4[illegible] be presumed that they all received [illegible] ment However for the first [illegible] of the service, the number of fillings of permanent teeth exceeded one million This is the best evidence that progress is being made

The research work done by the school medical officers is important but not spectacular At the end of the report is a table of special inquiries and reports done in 1935, but this does not give a just idea of the amount of research carried out in field experiment and observation Various special clinics, such as those for rheumatism, goitre, nutrition, &c , are really research stations from which knowledge of disease can be obtained not available to us in other ways and which are helpful in building up the science of human biology upon which our system of medicine rests

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED DEC 19TH, 1936

Notifications —The following cases of infectious disease were notified during the week Small-pox, 0 , scarlet fever, 2053 , diphtheria, 1334 , enteric fever, 21 , pneumonia (primary or influenzal), 982 , puerperal fever, 31 , puerperal pyrexia, 106 , cerebro spinal fever, 18 , acute poliomyelitis, 7 , acute polio encephalitis, 1 , encephalitis lethargica, 5 , dysentery, 29 , ophthalmia neonatorum, 71 No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Dec 25th was 3207 which included Scarlet fever, 988 diphtheria 1069 , measles 18 whooping cough 391 puerperal fever 14 mothers (plus 7 babies) encephalitis lethargica 284 , poliomyelitis 4. At St Margaret s Hospital there were 10 babies (plus 4 mothers) with ophthalmia neonatorum

Deaths —In 122 great towns, including London, there was no death from small-pox or enteric fever, 3 (0) from measles, 5 (1) from scarlet fever, 16 (4) from whooping-cough, 36 (2) from diphtheria, 44 (9) from diarrhœa and enteritis under two years, and 57 (12) from influenza The figures in parentheses are those for London itself

Doncaster reported 3 deaths from scarlet fever Fatal cases of diphtheria were reported from 22 great towns, Liverpool 8, Hull 5, Birmingham 3

The number of stillbirths notified during the week was 254 (corresponding to a rate of 41 per 1000 total births), including 32 in London

PANEL AND CONTRACT PRACTICE

The Capitation Fee for Adolescents

THE Government is proposing to extend medical (not sickness) benefit under the National Health Insurance Act to boys and girls of 14–16 who are in insurable occupations—estimated at about a million The benefit to be offered will be identical with that available to other insured persons except that young persons will not have to wait so long before receiving dental benefit From the practitioner's standpoint the terms will be the same except that as there is no sickness benefit there will, strictly speaking, be no sickness certification At a conference with representatives of the Insurance Acts Committee on Nov 4th the Ministry tentatively suggested a capitation fee of 6*s* (instead of the usual 9*s*) on the grounds (1) that practitioners will have no bother about certificates, and (2) that these adolescents will need less attention than ordinary panel patients The representatives of the Insurance Acts Committee said that they could not for one moment accept this second suggestion—that the medical care of young persons will prove less onerous—and in this they were supported by a leading article in THE LANCET of Dec 5th In a statement of their views the Committee expressed their astonishment that the Ministry should make such a suggestion and said that while the services given by practitioners to young people are different in kind they are more rather than less important than those rendered to older members of the community The Ministry s proposal to remunerate insurance practitioners at a cut rate for these services would damage national health insurance as an instrument of positive health—is opposed to its function of healing established disease—and would not encourage them to give the full preventive and curative service needed at the difficult time of transition between school life and wage earning

It is ' said the Committee "a retrograde and reactionary proposal" Moreover, the selection of a group of insured persons for whom a different capitation rate should be paid was opposed to the principle underlying the existing basis of remuneration and if it were introduced the Committee would have to consider its wider application in national health insurance and especially its application to the increasing proportion of old people in the community and to women

After pointing out objections to direct payment to approved societies for the purpose of dental benefit—which "can only, under existing arrangements, aggravate the existing inequalities in relation to additional benefits"—the Committee went on to question the advantage supposed to be gained by the practitioner by lessening of certification "Although," they admitted, "he will not be required to undertake the actual filling in of national health insurance certificates, his responsibility in so far as certification is necessary for other purposes remains unchanged For example, his employer will require certification of evidence of incapacity in most cases"

On these grounds the Insurance Acts Committee decided that unless an offer of the standard capitation rate, less a deduction of not more than 5 per cent in respect of certification, were made, they would summon a special conference of local medical and panel committees and recommend it not to accept the Ministry's proposals On Christmas Eve the Ministry's reply was received On the general question of the amount of care involved it said that while the Minister "remains satisfied that persons within the age group in question are likely, having regard to their comparatively low sickness experience, to make fewer demands on the services of practitioners than persons of older ages, he does not wish to press this point unduly, since he recognises that in the interests of public health it is desirable that juvenile workers should remain as far as possible under medical supervision " As for certificates, the Minister maintains that account must be taken not only of the actual work of issuing them but also of the extra visits paid by patients merely to obtain them , and he still contends that, despite the possible demands of employers, adolescents will give the practitioner relatively little trouble in certification In all the circumstances, he adds, he is "prepared to provide for a capitation fee of 7*s* 6*d* on the understanding that if the standard capitation fee for adults should be increased or reduced in future the rate for juveniles should be varied proportionately

The Insurance Acts Committee receiving this reply have summoned a conference of local medical and panel committees for Thursday next Jan 7th at 2 P M It will be observed they say that while the original contention of the Ministry that less work will be involved in the care of these young adolescents is not pressed certification has been valued for the purposes of the deduction at 1*s* 6*d* and a capitation fee of 7*s* 6*d* offered The committee will recommend the conference to reject this offer

MEDICAL NEWS

Society of Apothecaries of London

At recent examinations the following candidates were successful —

Surgery—G F C Harvey Univ of Manch., G G Sahasrabuddhe, Univ of Bombay and West London Hosp and J S Wood Univ of Liverp

Medicine—J T Boocock Univ of Leeds and J S Wood Univ of Liverp

Forensic Medicine.—J S Wood Univ of Liverp

Midwifery—J R Audy and J M Lea Guy s Hosp J E R Palmer St. Mary s Hosp and O Rochlin Univ of Melb and London Hosp

The following candidates, having completed the final examination are granted the diploma of the society entitling them to practise medicine surgery and midwifery G F C Harvey J M Lea, and J S Wood.

Royal College of Surgeons of England

A special lecture on the treatment of cardiac ischæmia will be given by Mr Laurence O'Shaughnessy in the lecture theatre of the Royal College of Surgeons on Friday Jan 15th at 5 P.M. Viscount Dawson of Penn president of the Royal College of Physicians, will give a short introductory address

University of Leeds

At the annual dinner of the Old Students Association held on Dec 10th Prof C M Gillespie anounced that the University Grants Committee of the Treasury had voted a sum of £15 000 towards the scheme for providing suitable accommodation for the students union Encouraged by the past and present students action in having collected some £4000 Mr W Riley Smith made the handsome donation *of £25 000 last* June The sum of £50 000 would have been required to carry out the original plans but these may be slightly modified and the work can now be started with confidence It is hoped that the *further sum of £5000 needed for equipment* will soon be forthcoming Though the site that has been reserved will be within the area occupied by the greatly extended buildings of the University it is not far from the medical school and the infirmary and will it is hoped act as a bond of union between the various faculties of the University

International Hospital Congress at Paris

The next International Hospital Congress will take place in Paris from July 6th to 11th in the Arts and Professions Building 9 bis avenue d Iéna Dr René Sand Dr W Alter and Monsieur Sarraz Bournet will represent the International Hospital Association on the committee and a programme of lectures and discussions has been prepared including French German Italian, and English speakers on the national planning of hospital services Other subjects to be dealt with are: hospital visiting; the rights of the hospital in regard to case-histories of patients general nursing; hospital finance and publicity; and the hospitalisation of mental cases Arrangements are being made to organise a visit of several days duration to the Lyons district for the week immediately preceding the congress The hospitals of Lyons the sanatoria of the Alps and the hospices of Beaune would be among those visited During the congress afternoon visits will be made to large hospitals including the Cancer Hospital at Villejuif The secretary of the association may be addressed at 87 Lord-street Liverpool

Pharmaceutical Society of Great Britain

A meeting of this society will be held at 17 Bloomsbury square, London W C. on Tuesday Jan. 12th at 8 30 P M when Dr F B Parsons, anæsthetist to Addenbrooke s Hospital Cambridge will lecture on anæsthetic agents

German Society for Study of the Circulation

The tenth congress of the Deutsche Gesellschaft für Kreislaufforschung will take place at Bad Nauheim on March 13th and 14th under the presidency of Prof E Stadler The main subject for discussion will be circulation and inner secretion and the principal speakers will be Sir Henry Dale H Rein (Göttingen) F Schellong (Heidelberg) W Haupt (Jena) M Bürger (Bonn) and G W Parade (Breslau) Those who wish to attend should communicate with Prof E. Koch at the Kerckhoff Institut Bad Nauheim before Feb 1st

Post-graduate Courses in Berlin

International post-graduate courses are to be held in Berlin on the following subjects internal medicine (Feb 22nd to March 6th); surgery and industrial diseases (April 5th to 10th) urology (April 12th to 17th) radiology (April 16th to 23rd) orthopædics (April 19th to 24th); tuberculosis (May 3rd to 8th); and homœopathy (April 5th to 30th) Monthly courses in all the special departments of medical science including practical work, will also be held. Particulars may be had from the information bureau of the Kaiserin Friedrich Haus Robert Koch Platz 7 Berlin N W 7

Appointments

BRUCE, H W., M D Lond F R.C.S Eng has been appointed Principal Medical Officer Central Administrative Staff of the London County Council

HOLDERNESS R C. M.B Lond D P H, Medical Officer of Health and School Medical Officer for Loughborough

St Mary's Hospital for Women and Children Plaistow—The following appointments are announced —

GORDON W H, M D Glasg D O M.S. D I H Hon Ophthalmic Surgeon;

APPLIN H W M B Lond D O M S Hon Ophthalmic Surgeon and

ELGOOD C. D M Oxon M R C.P Lond., Hon. Assistant Physician

Certifying Surgeons under the Factory and Workshop Acts Dr D H S Boyd (Hungerford District Berkshire)

Medical Referee under the Workmen s Compensation Act 1925 D L DAVIES M.S. M D F R C.S of Cardiff for all County Court Districts at present comprised in Circuit Nos. 24 and 30 for Ophthalmic Cases

Subject to confirmation.

Births, Marriages, and Deaths

BIRTHS

LLOYD STILL.—On Dec 31st at Welbeck street W the wife of Captain R M Lloyd Still of a son

MARRIAGES

GRACE—DISNEY.—On Dec 19th at All Saints Church Ottawa Archibald John Grace, F R C.S. to Mary Kathleen younger daughter of the Rev R B Disney of Lydon Rugby

JOLLIFFE—WALLIS.—On Dec. 19th quietly at Christ Church Folkestone, William Anthony Jolliffe Surg.-Comdr R N to Eileen Mary Wallis.

DEATHS

BERRY.—On Dec 14th at Southport Australia Robert Newton Berry M R.C.S Eng J P eldest son of the late Thomas Darby of Curry Rivel Somerset, in his [illegible] year

BOWSER.—On Dec 27th at Penrith J Edward Bowser M B C M Edin

DAVIES.—On Dec 25th at Kingston Hill, Percy Vernon Davies M R.C.S. Eng, Medical Superintendent of the Kingston and District Hospital

GODSON.—On Dec [illegible]th, at Blurring Crags Windermere Francis Arthur Godson M B Camb

HASLACHER.—On Dec 26th, suddenly at Arosa, Switzerland Francis Joseph Maria Haslacher M B Lond., F R C S Eng of Burton-court Chelsea aged 63

LENDON.—On Dec [illegible]th at Holland Park-avenue W Edwin Harding Lendon D M Oxon

MARTIN.—On Dec 22nd in London Edward Fuller Martin M D Edin of Weston-super-Mare in his [illegible]th year

SAINSBURY.—On Dec 29th Harrington Sainsbury O B E M D., F R C P Lond in his [illegible]th year

TIDBURY.—On Dec 22nd at Woking Lieut.-Col. Jam[illegible] O B E. R.A.M.C. retd

N B.—A fee of 7s 6d is charged for the insertion of Births Marriages and Deaths

NOTES, COMMENTS, AND ABSTRACTS

PRECOCIOUS PEOPLE *

By C R Croft, D M, M R C P
MEDICAL REGISTRAR AT THE PRINCE OF WALES'S HOSPITAL PLYMOUTH

There is a French proverb to the effect that "It is not sufficient to run fast, you must also start in time" On the other hand it is said that the precocious child is like an early riser, conceited all the forenoon of life, stupid and uninteresting all the afternoon and evening It seems to be a popular idea that those whose mental powers develop precociously in childhood are closely related to the degenerate, imbecile, and insane, and that they come to no good or die prematurely or unhappily Unfortunately medical literature provides only a few studies of precocity and these are mainly devoted to precocity in the sexual sphere

Of the various forms of intellectual precocity, the first may be called "normal," because it is merely an early manifestation of mental development of the highest adult type—sometimes rising towards what is called the *intellectus universalis* Another form is the one sided precocity in which a single faculty is exalted at the expense of others, as in *idiots savants* Thirdly there is the morbid or forced precocity, "psychasthenic precocity," the result of over-pressure and likely to be barren It was of this type, which he related to what we know as the "acidosis type," that Guthrie remarked "The precocious child is not necessarily a genius, but by careful management he may at least be prevented from becoming a failure" Fourthly there has long been a text-book tradition that tumours of the pineal gland are associated with precocious mentality

The Universal Intellect

Of the first group, having the intellectus universalis, Goethe is quoted as the finest example At nine he understood German, French, Latin, Greek, and had learnt Italian incidentally by hearing his sister take lessons in the language while he himself was engaged in his own studies One teacher claimed him as a predestined man of science, another as a brilliant artist, a third as a theologian, a fourth as a courtier, a fifth as a diplomat, and a sixth as a jurist, and it is true that in most of these rôles he excelled , though it is curious that apparently no one predicted that he would be a poet It is of Goethe that Napoleon said, "voilà un homme" It is interesting to note that at the age of 17 he was confined to bed for many months as a result of hæmorrhage He died at 83

Next we may take Dr Thomas Young who died at 56 At 2 years old he could read fluently and before he was 4 he had read the Bible twice. Before leaving school at 13, apart from the standard Greek and Latin of the day, he had got through six chapters of the Hebrew Bible, had learnt to use the lathe, and had made a telescope and a microscope The Italian, Persian, Syrian, and Chaldee languages all occupied his attention, and later he added Samaritan, Arabic, Turkish, and Ethiopian. Despite his knowledge of natural philosophy he was one of the less successful products of St Bartholomew's Hospital, and his later activities included the discovery of the undulatory theory of light, the deciphering of Egyptian hieroglyphics, the ascertaining of the length of the seconds' pendulum, and the superintending of the nautical almanac

Such recitations of virtue unlike the recitation of vice become tedious , but I cannot leave the subject without quoting the astonishing story of a boy called Clench, who was examined at the age of 11 by Pepys and Evelyn together The following is a quotation from Evelyn's diary —

> "There was not anything," Evelyn says, "in chronology, history, geography, astronomy, courses of the stars, longitude, latitude, doctrine of the spheres, courses and sources of rivers, creeks, harbours, eminent cities boundaries and bearings of countries, not only in Europe but in any other part of the earth, which he did not readily resolve and demonstrate his knowledge of He was not only able to repeat the famous things which are left to us in any of the Greek or Roman histories, Monarchies, Republics, Wars, Colonies, exploits by sea and land, but all the sacred stories of the old and new Testament, the succession of all the Monarchies, Babylonian, Persian, Greek, Roman, with all the lower Emperors, Princes, Heresiarchs, and councils,—what they were called about, what they determined , or in the controversy about Easter, the tenets of the Gnostics, Sabellians, Arians, Nestorians , the difference between St Cyprian and Stephen about rebaptization, the Schisms"

He answered questions on synchronisms, Olympic years, civil laws, and on the digest and code, and gave a stupendous account of both natural and moral philosophy, and even in metaphysics. "He was perfect in Arithmetic, Latin authors and French, and was newly entered into Greek." "He was as beautiful and lovely in countenance as in knowledge," and appears to have had very pleasant manners The only criticism one can level against this examination is that it took place at the Admiralty, and after dinner I have been entirely unable to trace the boy's subsequent career His father who was a doctor was murdered in his coach and that is all I can find out about him. Evelyn's own son, who died, it seems, of malaria as a boy, had something of the same brilliance, and his achievements are also recorded.

Taking a few great names at random we find marked precocity in John Stuart Mill, who died aged 67, in Leonardo de Vinci, who died at the same age, and in Sir Christopher Wren who died at 91 Isaac Newton had the three great discoveries conceived in his mind before he was 24, and died at 75 Other great men obviously very precocious, but whose records are less complete, include James Watt (83) , Haller who besides his scientific achievements—he first appreciated the mechanism of respiration—was also an administrator and a poet (70), Bacon, that wisest, brightest, meanest of mankind (65) , and Aristotle (62), Galileo (78), and Grotius or van Groot (62)

Following the work of James Sully, Guthrie points out that the order of development of mental precocity follows the normal development of mental faculties. These may be placed in three groups first, those subserving sensory impressions, in which precocity is shown by musicians and artists , secondly, faculties dependent on the formation of mental images, illustrated by the poets and fiction-writers and lastly, faculties dependent on the formation of abstract ideas, which are exhibited by the philosophers. In precocity musicians are the most striking and philosophers the least, while the poets and fiction writers are intermediate, and scientists appear to fall between the second and third groups

One sided Development

At one end of the scale there is exultation of all faculties, the intellectus universalis , at the other end is great development of one faculty while others are in abeyance It is here as I have said, that we find the idiots savants These have been studied by Langdon Down, and he quotes remarkable cases where there was great aptitude only for mental arithmetic and calculation, or mimetic faculty, manual skill and dexterity, or musical ability

---

* Based on a paper read to the Plymouth Medical Society on Nov 13th 1936

A striking example of this kind was Blind Black Tom of Boston, Massachusetts He was born a slave in 1850 a blind imbecile of the lowest negro type coal black, with protruding heels, ape-like jaw and blubber lips constantly open. At 12 he was exhibited all over the State as a musical prodigy Although incapable of understanding the simplest conversation, and like a child of 3 in conduct he had a large repertoire of classical and operatic music which he played entirely by ear He could repeat any piece of music after once hearing it played and could supply the bass to the treble of music heard for the first time. One of his turns was to play seated with his back to the keyboard. His memory was astonishing he could repeat a conversation fifteen minutes in length without loss of a syllable yet without understanding a word of it It was purely an auditory memory that compares somewhat with the calculating prodigies.

From abnormal types of this kind we work upwards to the men of brilliant qualities whose faculties lie in some special direction *Musicians* supply the most surprising and constant examples; in fact it may be said that only one great composer—namely Wagner—failed to show a very early bent

It would be tedious to enumerate instances of musical precocity Mozart played minuets at 4 and in his fifth year he composed concertos Schubert was composing at 11, and even the backward Wagner at the age of 15 became inspired with an overpowering passion for the art after hearing Beethoven symphonies Mendelssohn first played in public at 0 and wrote his first work at 11 There is of course among musicians a very strong hereditary talent of which Bach is perhaps the most remarkable instance, the family being important in the history of music for two hundred years. Of forty composers whose records are collected by Sully thirty-eight (05 per cent.) showed great bent before they were 20; among twenty seven of them ten began composing before 15 fourteen between 15 and 20 and only three after 20[4]

Mathematicians seem to come next; that is those with the power of calculation independent of profound thought—another type of idiots savants. Those capable of rising to greatness in this direction must clearly have a full share of the intellectus universalis but one or two examples of the calculating type may be of interest. It seems possible that the power of rapid calculation too rapid to be based on a process of reasoning is related in some way in its mental process to the musicians control over the musical scale, and may be compared with musicians tone-images The scale of figures is of the same kind as the scale of musical notes

George Bidder who died in 1878 at the age of 74 was perhaps the most celebrated calculating boy His history is of some interest. He was born at Moretonhampstead and his father took him round on exhibition. From this he was rescued by Sir John Herschel and sent to school at Edinburgh He became connected with the development of the railways *in England Belgium and Scandinavia* and his principal memorial is Victoria Docks, London which he designed He was also a founder of the Electric Telegraph Company He is said to have been unsurpassed for calculation, but clearly his work does not lie in the realm of genius.

Painters can be placed next with sculptors Much recitation of their precocity would be boring but a remarkable example is George Morland who is said to have taken pencil and crayon in hand as soon as he left the cradle. Sketches of his at 4 5 and 0 were exhibited at the Society of Artists Common ages for the production of notable work vary from 0 to 14 and among the young artists may be mentioned Montegna Titian Tintoretto Michael Angelo Murillo Holbein Sir Thomas Lawrence Turner Ingres Wilkie, van Dyck and Rubens. Of sculptors can be mentioned Canova and Flaxman.

Of fifty-eight artists forty two (75 per cent.) showed decided skill before 15 years and 80 per cent before 20 In a group *of forty two, twenty-eight* (07 per cent.) were famous before they were 25 None can be traced to whom fame came after 40 years.

Among the *poets* great precocity is seen in Goethe, de Musset, Victor Hugo Cowley Pope Byron, and Coleridge Elizabeth Barrett Browning read Homer in Greek at 8 and wrote poetry at the same age Of 40 poets 66 per cent wrote before 20 92 per cent wrote before 80 and 56 per cent were famous at 25

Novelists—Remarkable precocity was shown by Scott Dickens Lytton Balzac, and Hoffmann also the Brontës and Miss Burney Of twenty-eight novelists 75 per cent showed power before 20 but there are a number of instances of late exhibition of power of whom Defoe, de Morgan, Hardy and Conrad come to mind Although promise is shown thus early in novelists their fame is delayed though 80 per cent. have reached distinction at 40

We then turn to *scholars* and *historians* and here are again approaching the pure intellectus universalis unaccompanied by special development of talent Nevertheless one factor is of special importance in this group and that is the power of memory Macaulay is one of the most famous examples of this At the age of 4 he was taken to the Orford Collection and he remembered the catalogue for ever after Before he was 8 he had written a compendium of universal history and other heavy works. Of art he confessed himself quite ignorant and he recoiled from mathematical studies Many scholars showed similar traits. Memory is the foundation of scholarship and the secret of success in *examinations It may be said that no great man* ever had a bad memory but a good memory does not make a great man.

As examples of precocity in scholarship may be mentioned Grotius, Porson, Macaulay Thirlwall and Gibbon. The records of a group of scholars shows that 83 per cent were definitely precocious and while only 20 per cent achieved distinction at 25 90 per cent were recognised at 40

The next in the scale show a larger infusion of intellectus universalis—the *men of science* Among them are many instances of juvenile distinction Most of them produced outstanding contributions to knowledge in their early twenties Galileo as a boy discovered that the beats of a pendulum are isochronous. Haller the father of physiology was exceedingly precocious; and so as I have said already were Isaac Newton and James Watt Naturalists are similarly endowed. Linnaeus and Cuvier are examples of these and although Harvey did not publish his discovery until the age of 50 he expounded it 12 years before this. Benjamin Franklin making his first and this a discovery of the first order at the age of 50, is almost unique He is also peculiar in being one of the few great discoverers who died insane.

It is calculated that 75 per cent of men of science have shown distinct promise before 20 and 70 per cent are famous at 30 In about 8 per cent only was fame delayed until after 40

Among *philosophers* Berkeley is the most astonishing example His New Theory of Vision was published at the age of 21 but conceived at 18 Heine and J S Mill are also instances of precocious mentality Leibnitz was busy at 17 Many however only achieved distinction after 50 such as Descartes Hobbes and Locke with Kant at 40 Of a group of thirty-six only 51 per cent produced work before 20 and 75 per cent under 30, while 23 per cent had to wait for renown until they were past 50

Summarising the results of an analysis of this kind we find that distinct promise is shown before the age of 20 as follows —

Musicians	95	Poets Novelists Men of Science	7
Artists	80		
Scholars	83	Philosophers	[illegible]

Finally we come to the people who may be called *leaders of men* This group includes military, political, and industrial leaders, and their characteristics are peculiar, for history is singularly silent as regards their early precocity, though their great work is usually completed at an early age, and if they survive this period their reputation is apt to suffer An exception is Chenghis Kahn—perhaps the greatest conqueror the world has seen—who did not begin his greater campaigns until the age of 40, but died, still a campaigner, at the age of 65, with an empire extending from the Dnieper river to the China Sea Alexander the Great on the other hand began his career of conquest at 20 and his work was done at 32 Cæsar's main activity extended over about 12 years until he was murdered at 56 Napoleon was not particularly distinguished as a young officer His active period extended over only 20 years and he was only 46 when Waterloo was fought Wellington —" my dull boy Arthur " as his mother called him—was 55 on the same occasion Marlborough's great period was 46–50 Charlemagne finished fighting at 55 and died at 72 Nelson died with his work done at the age of 47 The gallant escapades of his youth, which largely won his recognition, were partly dependent on the fact, as he himself admitted, that he had no sense of fear Mussolini, who is 53, was unheard of more than 15 years ago Hitler is 47 and has only been known outside Germany for some 11 years It is clearly not the man who plods with peacetime professional grace to the top of the tree who will be the great war commander

It seems appropriate to consider why the biological details of persons of this group should differ so markedly from those of the other groups, whose names like theirs will ever be on men's lips I see no other alternative than to regard them as of a fundamentally different biological type in their achievements

The Physical Side

We turn finally to the physical aspect of precocious individuals There are two main clear cut groups—namely, those with pineal tumour and those with suprarenal tumour There is no doubt that precocious sexual development is a definite clinical sign in tumours of the pineal gland, exhibited as enlarged genitalia in cases occurring before puberty, as was first shown by Ogle in 1899 Recent experimental work has confirmed this Hanson reports from experiments in rats that if a pineal extract is injected into rats and this injection continued through nine or ten generations there is a progressive acceleration in development of size and of sexual maturity It seems that a strong case is being made for including the pineal gland among the endocrines What evidence is there that the pineal affects mental development? It is at present clinical rather than experimental Horrax and Bailey in 1925 described 12 cases of pineal tumour from Cushing's clinic Of these cases 5 were developed before puberty and 4 were in boys Of these 4 boys 3 showed mental precocity and they deserve description

1 Aged 6 "Developed exceptionally well Tall for age, genitalia normal "

2 Aged 11 Full sex characters and deep voice, "accompanying his physical and sexual maturity there was a corresponding intellectual maturity in advance of his age "

3 Aged 3 Two teeth at 2 months, seven teeth at 4 months talking at 8 months, walking at 9 months Extremely intelligent and far advanced for his age Learned to ride a velocipede and had been roller skating during this his third year "

Further cases of pre-puberty pineal tumours are recorded, to a total of 11 All are in boys and 6 showed mental precocity Perhaps the ancients were not far wrong in regarding the pineal as the seat of the soul

The relationship of precocious sexual development to suprarenal tumours was first established by Bulloch and Sequeira (1905) Their paper describes 12 cases of precocious sexual development with suprarenal tumour of which 10 were female and 2 male Of 13 further cases of tumour without precocious development, 8 were female, 4 male, and 1 of doubtful sex In a further collection, by Jump, Beates, and Babcock, of 18 cases, 14 were girls and 4 boys They remark "some showed mental precocity, though the majority were probably mentally dull "

So far as sexual precocity is concerned, it seems that in girls the condition is usually associated with suprarenal disorder, while in boys the association is more commonly with a disordered pineal gland, and mental precocity is often present also I do not propose to draw any conclusions from these facts But if speculation were permissible one might visualise not only a time when our mental deficients will be rendered normal with pineal extracts, but ordinary intelligence may be made extraordinary by the same means Let us hope, then, that its use will be carefully regulated. The idea of a Leonardo de Vinci to paint your house a Wren to mend it and a Macaulay, a Lenin, and a Hitler on the parish council cannot be anything but a nightmare

I wish to record my thanks to Mr J S Shields of the B M A library for his great help in securing the variety of books for which I asked him, often from libraries other than his own Also amongst the shades, I must thank in particular those of Dr L G Guthrie and Prof James Sully, whose work has been freely used

THE PUBLIC AUTHORITIES PROTECTION ACT

THE Law Revision Committee, appointed by the Lord Chancellor to consider the alteration of legal maxims and doctrines in the light of the statute law and judicial decisions, has produced a fifth interim report (Cmd. 5334, H M Stationery Office 9*d*) which has a possible bearing on the liability of medical officers The Committee has been delving into the uninspiring mysteries of the statutes of limitation which impose various complicated time-limits on the right to bring legal proceedings After a prolonged examination of the general limitations which no layman will lightly essay to comprehend, the report deals with the time-limit under Section 1 of the Public Authorities Protection Act, 1893—a statute not infrequently pleaded in defending actions arising out of treatment in local authorities hospitals

The section relates to proceedings, whether criminal or civil, against any person for any act done in pursuance of an Act of Parliament, or of any public duty or authority, or in respect of any alleged neglect or default in the execution of any such act, duty, or authority Such proceedings shall not lie or be instituted unless begun within six months after the act, neglect, or default complained of, " or, in the case of a continuance of injury or damage, within six months next after the ceasing thereof." The " continuance of injury or damage," mentioned in the passage quoted above in inverted commas, has been interpreted by the judges to mean the continuance of the act which caused the damage There are other complications which the curious may pursue in the reports of cases like Venn *v* Todesco (1926, 2 K.B 227) where the medical officers of the Croydon Borough Hospital were said to have been at fault and Harnett *v.* Fisher (1927 A.C. 580), which indicated the possible clash between the Lunacy Act and the Act of 1893.

Be those problems what they may, the Law Revision Committee now recommends that the six months time-limit under the Public Authorities Protection Act 1893 should be enlarged to twelve. The policy of the 1893 Act, it says, is quite clear—namely, to protect absolutely the acts of public officials, after a very short lapse of time, from challenge in the courts. The Committee cryptically remarks that such a policy might be justifiable in the case of important administrative actions where serious consequences might follow if the actions were impugned after a long interval. But the real use of the statute has been found to lie in protecting "cases of negligence of municipal tram drivers or medical officers and the like." This slightly contemptuous description of the classes of public servant concerned is followed by the observation that "there seems no very good reason why such cases should be given special treatment merely because the wrong-doer is paid from public funds."

The suggested extension of the time-limit under the 1893 Act is the more striking because the Law Revision Committee elsewhere in its report is mainly recommending reductions rather than extensions. The general object of the Statutes of Limitation, as the report makes clear, is not merely to prevent delay in the making of claims; they aim at putting a certain end to litigation and at preventing the resurrection of old claims, whether there has been delay or not. Even a medical officer (who, after all, does not practise for private profit) may be at a disadvantage in defending himself against claims for alleged negligence when they arise out of some *brief incident of a busy day more than six months* before.

FIRE PRECAUTIONS AT HOSPITALS

TEN years ago the management committee of King Edward's Hospital Fund for London took counsel with the chief officer of the London Fire Brigade about the precautions desirable to avoid the danger of fire in hospitals or to mitigate its results. The result was the issue of an important memorandum. Happily fires occur very rarely in London hospitals, but it requires day-by-day vigilance to forestall the risk, and to this vigilance the Hospital Fund's memorandum has been a useful stimulus. The memorandum has now been revised up to November, 1936, and can be obtained from George Barber and Son, Ltd. (23, Furnival-street, London, E.C.4. 6*d.* post free). We take this opportunity of extracting from the memorandum the steps to be taken in case fire *did* break out. These are Items 55 to 62. Item 54 dealt with the arrangements for a responsible official to be informed at the same time as the fire brigade is summoned.

> Upon the discovery of a fire all doors and windows in the vicinity should be kept closed as far as possible in order to exclude draught.
>
> The person discovering the fire should, after having made sure that the alarm has been given and that the fire brigade has been summoned, *attack the fire by means of the* appliances available.
>
> If hydrants are provided, the hose should be extended from the nearest hydrant, care being taken to keep the hose free from kinks; but the water should not be turned on unless it is evident that the extinguishers and fire buckets are insufficient to extinguish the fire.
>
> If the fire is of an electrical nature, sand only should be used in the first instance, and the current should be cut off.
>
> For oil, spirit, and fat fires, foam type extinguishers should be used.
>
> For a person's clothing alight, or if the fire is small, wraps, blankets, rugs, &c., should be used.
>
> Nurses on duty should move patients from the proximity of the fire or if necessary evacuate the ward. Patients may be removed on bedding if essential, but beds or furniture should not be removed.
>
> The officers who have been previously detailed for the purpose should proceed to the various wards, &c., in order to allay any tendency towards panic, while the remainder of the staff should proceed to whatever stations have been allotted to them, or should leave the building.

A NEW HEARING AID

THE type of hearing-aid in which amplification is obtained by means of thermionic valves is deservedly becoming more popular. It has several advantages over the more familiar simple microphone type, among which are improvement of hearing at a distance, greater freedom from distortion, and (most important) the ability to increase the amplification at any desired part of the scale. The disadvantages of size and weight have recently been lessened by improvements in design, and a new model submitted to us by Messrs. Auraphone Ltd., of 120, Wigmore-street, London, W.1, is very compact, being contained in a neat box measuring 6¼ × 4¾ × 1 7/16 in. Two valves are employed, actuated by a dry high tension battery and a small low tension accumulator, for which a trickle-charger can be provided. The tone-control is adjusted by a recessed screw accessible with a screwdriver, and is not intended to be moved by the patient. For the receiver a specially packed carbon-granule microphone is employed which operates in any position, and a choice is available from six microphones having different degrees of power and freedom from background noises. The standard earpiece is light and neat, and is held in position by a spring band, or a midget earpiece may be used, of which there is a great variety to ensure a comfortable fit in the concha; alternatively a bone-conductor may be employed, and this is provided with a more powerful spring band to ensure good contact. The case may be carried by a sling worn over the shoulder under the coat, by a strong clip fixed to waistband or braces, or in a lady's handbag with space provided for receiver and earpiece as well as for handkerchief and other necessaries. The model examined worked very well with a minimum of distortion; the design has been carefully thought out, and the price, 12 guineas with the standard earpiece, is a moderate one. The instrument may be taken on trial before purchase—an important provision which should be, but is not, always observed by makers of hearing aids.

LECTURES ON AIR-RAID PRECAUTIONS

THE London Post Office Corps of the St. John Ambulance Brigade have arranged a course of lectures which will be held at Marylebone Town Hall on Fridays at 8 P.M. from Jan. 15th to Feb. 12th. The subjects to be dealt with include the effects of weather and topographical features, the classification of gases and their appropriate first-aid treatment, protective clothing, decontamination, and protection of the eyes and lungs. Demonstrations of how to use gas mask Mark IV, and how to arrange for collective protection and protection in rooms will also be given. The fee for the course is 5s., and application for admission should be made to the divisional superintendent, 55/1 W.D.O. Division, St. John Ambulance Brigade, Western District Post Office, W.1.

THE CIBA CALENDAR

THE calendar issued by Ciba Ltd., 40, Southwark-street, S.E.1, for 1937 combines the function of a monthly and daily calendar in a convenient and practical manner. The days of the present and succeeding months are shown clearly on each page and ample space is left for entries. The leaves are mounted in the form of a file on a pencil stand which can be placed on the desk.

ald (1935) have demonstrated a similar subcutaneous injection of gr 1/30 of the choline esterase activity of the nately 15 per cent

ns occur in the choline esterase era of different animal species and iduals of a given species (Stedman Easson 1932) Human serum is igh in the scale. Choline esterase it from the cerebro-spinal fluid of mals although appreciable quantities n substance (Stedman and Stedman all, and Ettinger (1935) determined ity of 200 human sera normal and l although large variations were relationship to health age sex or In a further series of 100 sera ound a fairly smooth distribution ighest readings were approximately as the lowest. Repeated estima intervals, and also over a period howed in individual cases a varia 15 per cent. In a study of the luction of coronary thrombosis dure in dogs Hall Ettinger, and und the normal serum esterase nparatively narrow range for each hile the continuous daily injection holine did not produce any marked erase value from week to week of the animal.

ravis contradictory results have edman (1935) determined the tent of defibrinated blood from a suffering from this disease and ch exhibited a tendency to be ith the normals Hicks (1936), ly examinations of a single case eriod of 5 months found that blood of this patient show any sterase activity which increased of the disease and diminished Prostigmin injection Samples m clinical conditions could be as to the relative severity of

importance of the cholinergic impulses at the preganglionic pathetic system (Feldberg and parasympathetic system (Dale and at the muscle end plates or system (Dale Feldberg and Dale and Feldberg 1936) the oline esterase activity of the patients has been undertaken what correlation if any could the clinical state of the patient ity of the serum Through the Walker it has been suffering from m en extensively already Hospital.

frontal sinuses, but the findings must be interpreted with discretion , much relative dullness of one antrum is especially significant, but may be the result of old cured inflammation , on the other hand, one occasionally finds pus in an antrum which lights up clearly Transillumination gives less assistance in the frontal sinuses, for they are more often asymmetrical If one sinus is dark and the other lights clearly, this may be due to disease or to a small cavity with thick walls But the method is still useful in conjunction with skiagraphy, for, if the dark sinus is thus shown to be of normal size, it is probably infected. A series of skiagrams is helpful particularly if a fluid level is shown , a thickened lining is proof of an unhealthy condition, but may be the result of allergy or of past inflammation, and not of sepsis Neither the making nor the interpretation of these skiagrams is easy , it is most important that standardised positions be chosen and accurately used Exploration gives positive results, but is difficult except in the case of the antrum , normal saline should be injected into the cavity and sucked out with the syringe If pus be found the diagnosis is established , when a clear lotion is returned, if sinusitis be strongly suspected, it should be submitted to bacteriological examination, for it may prove to be definitely infected , but I am not inclined to attach significance to a clear lotion containing a few bacteria

THE TONSILS

Next to the teeth the tonsils are the commonest source of focal sepsis Here, too, indiscriminate removal in rheumatic patients is strongly to be deprecated, though if no relief results less harm has been done than by wholesale extraction of the teeth

The diagnosis of tonsillar sepsis is easy in many cases but is difficult in others, and as usual it is much more difficult to exclude an unhealthy condition than to confirm it Many septic tonsils are quite small and "buried" or deeply placed behind the anterior pillars An important sign is redness of the anterior pillar , in typical cases this shows as a broad red band with a well defined outer margin, and often extends on to the palate in the region overlying the upper pole When the patient is anæmic, as many rheumatic people are, the contrast with the pallor of the rest of the fauces is very noticeable The tonsil should be squeezed, after cocainisation if necessary, with a flat instrument , the back of a nasopharyngeal mirror is very convenient, and may also be used to retract the pillar to aid inspection of a buried tonsil Another method is to aspirate the tonsil with a suction cup designed for the purpose, when pus will be drawn from any septic crypt If fluid pus oozes out of the crypts on pressure, it is sure evidence of sepsis Solid masses of cheesy material or epithelial debris are not uncommon in one or more crypts, but should not by themselves be taken as evidence of a toxic focus There is also a condition called pharyngokeratosis, in which yellowish white projecting nodules cover the tonsils, that is apt to be mistaken for chronic follicular tonsillitis but the nodules are firm and hard and are often to be seen beyond the tonsils, on the base of the tongue and on the pharyngeal wall , these are not a source of toxæmia The examination of a swab rubbed over the surface of the throat is of little value for numerous organisms, including streptococci are normally present in the mouth. It is much more helpful to examine a bead of pus expressed from a tonsillar crypt and carefully picked up on a swab, when a copious growth of *S hæmolyticus* or *S viridans* is significant Glands in the neck are often slightly enlarged and tender in chronic tonsillar sepsis, especially the so called "tonsillar" glands below the angle of the jaw near the carotid bifurcation , this is a valuable sign. I attach considerable importance to the history , the tonsils are suspect when a patient is subject to attacks of sore-throat, even though they appear healthy when examined during a quiescent period Sore throats are of still more significance when they are followed, as often happens, by increase of the rheumatic symptoms

Cases of mild tonsillar sepsis, especially if limited to a few crypts, can be improved and kept in better condition by syringing or wiping out the crypts with hydrogen peroxide or iodine, and the patient may be taught to do this for himself. Periodical aspiration with a suction cup is also useful Deep puncture with a galvanocautery point may be employed into or between the crypts , if applied to a crypt the point must be a fine one and be inserted well down to the bottom, or the crypt will merely be sealed up and absorption from it increased. But, when toxæmia has caused rheumatic symptoms, more thorough treatment is usually necessary The most satisfactory method of treatment is undoubtedly tonsillectomy With modern technique, and especially with particular care in the ligature of all bleeding points, the danger of this operation, even in elderly people, is very slight I have removed a tonsil, which was growing rapidly and which, it was thought, might contain a neoplasm, from a lady of over 80 years of age , healing and convalescence were as rapid and satisfactory as in any younger patient But many patients dread this operation, and many desire a method of treatment which does not involve absence from their work

An old method of treatment with caustics, used by Sir Morell Mackenzie, was revived some 18 years ago by Irwin Moore (1919) It consists in applying once or twice a week on a special applicator equal parts of caustic soda and hydrated lime made into a paste with absolute alcohol This is called "London paste" and produces after five seconds' application a deep red patch streaked with black hæmorrhagic areas and followed next day by a yellow slough. The procedure can be made painless by careful use of cocaine, but is not free from after pain , after some 6–8 applications the tonsil is considerably reduced in size, but I have not persevered to its complete ablation by this method

Of all forms of treatment, apart from tonsillectomy, diathermy coagulation is the most efficient It is not an easy method but, on the contrary, demands considerable technical skill, or harm instead of good may result Graham Brown (1932) of Brisbane has reported 6 cases in which toxæmic symptoms were seriously increased by diathermy of the tonsils, and in one of which subacute multiple articular rheumatism appeared for the first time during treatment The danger lies in producing a dense layer of fibrous tissue which seals or "bottles up" septic lymphoid tissue beneath it To avoid this it is essential to use a finely pointed electrode and to remove the tonsils systematically Pain during the procedure can be almost abolished by careful local anæsthesia I find very helpful the application to the area to be cauterised of a small pledget of cotton moistened with Bonain's solution, composed of equal parts of cocaine hydrochloride, menthol, and phenol, which liquefy to a syrup on mixing together If too much is done at a time considerable after pain is caused and the operator must endeavour to strike a correct balance by doing enough to make progress while causing little pain; with experience this will be found quite feasible The treatment may be applied once a week or once a fortnight to each tonsil; it is often a good plan to treat alternate sides at each weekly sitting At this rate 3–4 months are usually required for complete removal. The greater part of the tonsil can be removed quite quickly but a number of treatments may be required for the destruction of the last deeply placed portions. The tissues are sterilised for some distance beyond the area of necrosis, so that rheumatic symptoms may be improved at an early stage of treatment

Some patients become free from symptoms and remain well over a long period with treatment short of complete removal. Others are symptom free for a time but relapse with subsequent reinfection of the tonsillar remnants and in others again, a satisfactory result is only to be obtained by complete ablation As might be expected the patients who refuse tonsillectomy are apt to be nervous and intolerant of pain and are therefore difficult subjects for this method of treatment Children are unsuitable and so also are those people who, in spite of training and of all gentleness retch and gag intractably when the throat is touched.

WITH SPECIAL REFERENCE TO MYASTHENIA GRAVIS

BY MURRAY MCGEORGE, M B N Z

(*From the Department of Medicine, British Postgraduate Medical School and Hammersmith Hospital*)

THE intense pharmacological effect of acetylcholine has been well known since its first description by Hunt and Taveau (1906) Dale (1914) analysed this effect and showed that acetylcholine had both a parasympathomimetic or muscarine action and an action resembling that of nicotine on ganglionic cells and muscle-fibres He also emphasised the extraordinary evanescence of this effect and suggested that it was probably due to hydrolysis into choline and acetic acid by an esterase in the blood

Loewi and his co workers (Loewi 1921 1922; Loewi and Navratil 1926) found that the physiological activities of the substance liberated in the *heart* on stimulation of the vagus nerve and of acetylcholine were indistinguishable and showed that both substances were destroyed by aqueous extracts of frog s heart an effect which was inhibited by eserine. Galehr and Plattner (19–7) in a study of the effect of defibrinated mammalian blood upon acetylcholine in vitro found that hydrolysis occurred with great rapidity; while Engelhardt and Loewi (1930) demonstrated the strong inhibitory action of eserine upon this hydrolysis Matthes (1930) showed further that *inhibition of esterase by eserine* which occurred even in such low concentration as one part in 30 millions, was reversible full esterase activity being restored when eserine had been removed by dialysis The action of eserine in protecting acetylcholine liberated from the superior cervical ganglion by stimulation of preganglionic fibres has been described by Feldberg and Gaddum (1934) while Jones and Todd (1935) have demonstrated a similar effect in man the subcutaneous injection of gr 1/30 of eserine *depressing the choline esterase activity of the* serum by approximately 15 per cent

Wide variations occur in the choline esterase activity of the sera of different animal species and also among individuals of a given species (Stedman Stedman and Easson 1932) *Human serum is* comparatively high in the scale Choline esterase is entirely absent from the cerebro spinal fluid of both man and animals although appreciable quantities occur in the brain substance (Stedman and Stedman 1935) Lucas Hall and Ettinger (1935) determined the esterase activity of 200 human sera normal and pathological and although large variations were noted no obvious relationship to health age, sex or diet was apparent In a further series of 100 sera Verebély (1936) found a fairly smooth distribution of activity the highest readings were approximately six times as great as the lowest Repeated estimations at two hourly intervals and also over a period of three months showed in individual cases a variation of less than 15 per cent In a study of the *experimental production of coronary thrombosis* and myocardial failure in dogs Hall Ettinger and Banting (1936) found the normal serum esterase value to have a comparatively narrow range for each individual animal, while the continuous daily injection of 50 mg of acetylcholine did not produce any marked change in the esterase value from week to week throughout the life of the animal

In myasthenia gravis contradictory results have been obtained. Stedman (1935) determined the choline esterase content of defibrinated blood from a number of patients suffering from this disease and obtained values which exhibited a tendency to be low as compared with the normals Hicks (1936) from a series of weekly examinations of a single case extending over a period of 5 months found that *at no time did the blood of this patient show any*thing but excessive esterase activity which increased with the severity of the disease and diminished with treatment by Prostigmin injection. Samples taken under unknown clinical conditions could be accurately estimated as to the relative severity of the disease

In view of the importance of the cholinergic transmission of nerve impulses at the preganglionic synapse of the sympathetic system (Feldberg and Gaddum 1934) in the parasympathetic system (Dale and Feldberg 1934) and at the muscle end plates of the voluntary motor system (Dale Feldberg and Vogt 1936 Brown Dale and Feldberg 1936) the estimation of the choline esterase activity of the sera from a series of patients has been undertaken *in order to determine what correlation if any could* be obtained between the clinical state of the patient and the esterase activity of the serum Through the kindness of Dr Mary Walker it has been possible to include two patients suffering from myasthenia gravis who had already been extensively studied by her in addition to a third case already present in the wards of the Hammersmith Hospital

METHOD

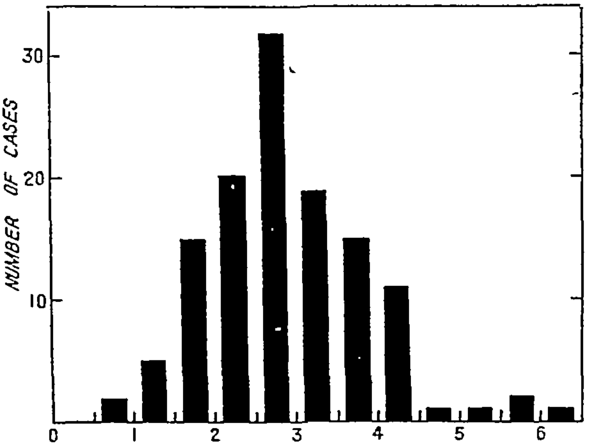
A method of estimation based on that of Stedman Stedman and White (1933) was employed

In a large test tube in a glass thermostat maintained at 30 C. 50 c.cm. of freshly distilled CO₂ free water was placed. To this was added 1 c.cm of cresol red indicator (B.D H.) and 1 5 c.cm of an acetylcholine substrate prepared by dissolving 1 gramme of acetylcholine [illegible] in 10 c cm of water In this solution 1 5 c cm. contained 150 mg of acetylcholine bromide, equivalent to 125 mg of acetylcholine chloride A few drops of 0 1 N NaOH were then added to adjust the reaction to pH 8 Comparison was made with a tube containing 50 c cm of a standard borate buffer and 1 c cm of cresol red indicator, tightly corked and also suspended in the water bath To the substrate 0 5 c cm of serum was then added, the reaction again adjusted to pH 8, and the tube stoppered with a rubber bung which was pierced by an intravenous needle connected by fine rubber tubing to a burette containing 0 01 N NaOH. Alkali was then added, drop by drop through the needle with constant shaking, to neutralise the acetic acid liberated and to maintain the solution at a constant reaction of pH 8 The burette was read at the end of 20 mins , the number of c cm of alkali required being a measure of the acetylcholine esterase activity of the serum Blank determinations without serum required 0 1 c cm of 0 01 N NaOH to maintain a constant reaction over this period, and this figure was consequently deducted from each reading

The figures used in the text to denote esterase activity are the number of c cm of 0 01 N NaOH required as above

RESULTS

Sera from 132 patients were examined, esterase determinations being made in most cases within a few days of admission to hospital These initial readings, arranged in groups according to the esterase activity of the serum, are set out in Table I, the results being summarised in the Figure



The choline esterase activity in 132 patients.
(For units see text)

The series includes a wide range of clinical types—patients healthy apart from some localised disability, patients suffering from malignant disease, toxæmic states, hypertension, congestive heart failure, disseminated sclerosis allergic diseases, thyrotoxicosis and myxœdema, psychoses, and myasthenia gravis A careful study of the order of occurrence of particular diseases, and in addition a detailed investigation of the case histories and clinical types of patients exhibiting either high or low esterase activity, failed to reveal any correlation between this factor and the temperature pulse rate, type or severity of disease, age, sex, or state of nutrition, or with the mental or physical constitution of the patient Thus cases of hypertension, congestive heart failure, or thyrotoxicosis occurred almost equally at all levels in the series while of 3 cases of myxœdema 2 showed comparatively low esterase activity, the third being among the highest recorded

Repeated estimations were made on 44 of these patients, in order to determine what variations if any occurred from time to time, and especially in association with changes in the clinical condition Of these, 13 (30 per cent) varied by less than 12 per cent. on repeated examination over a period of 3–8 weeks, while 31 (70 per cent) showed a variation of under 25 per cent Some typical results are shown in Table II

In 5 cases only did the esterase activity double or halve its value while the patient was under observation, and all these remained within the normal limits The greatest variation occurred in a patient aged 27 with

17th	1·6	June 6th	4·1		

Op =operation.

In 1 case of myxœdema the esterase activity declined steadily under treatment from 5·3 to 2·2 while another case of the same disease exhibited an almost equal increase

CHOLINE ESTERASE CHANGES IN MYASTHENIA GRAVIS

Three cases of myasthenia gravis included in the present series showed serum esterase activity of 1·0 2·6 and 4·4 units—i e well within the normal range as determined above and with little variation on repeated examination from day to day After the administration of a therapeutic dose of 3 mg of prostigmin however there was a sudden drop in esterase activity to ⅓–½ of the resting level with gradual restoration during the succeeding four or five hours towards the end of which period myasthenic symptoms were returning The results of a typical experiment are shown in Table III Thus the patients remained strong only during the period of artificial depression of the esterase level and relapsed as this returned to the previous value.

TABLE III

Effect of Prostigmin on Esterase Activity in Myasthenia Gravis

Time	Remarks.	Esterase activity		
		Case 1	Case 2	Case 3.
	Resting value	2·6	1·0	4·4
0	Prostigmin 3 mg	—	—	—
15 mins.	Patients strong	1·0	0·9	[illegible]
2 hrs	—	1·5	1·4	3·0
5 hrs	Patients drooping	2·1	1·8	3·7
6 hrs.	—	2·3	1·9	4·0

In a similar experiment in which a dose of 2·5 mg of prostigmin was administered to each of three non myasthenic patients a corresponding depression of esterase activity to approximately one-third of the resting level again occurred accompanied in from 10 to 15 minutes by severe visceral and tonic skeletal muscular activity The esterase values in Table IV were obtained —

TABLE IV

Effect of Prostigmin on Esterase Activity in Three Non-Myasthenic Patients

Time	Remarks	Esterase activity		
		Case A.	Case B	Case C
	Resting value	3·5	2·2	2·8
0	Prostigmin 2·5 mg	—	—	—
10 mins	—	1·1	0·9	1·0
10–15 mins	Visceral and motor responses	—	—	—
3 hrs	—	2·3	1·7	2·1
4½ hrs	—	3·1	2·0	2·0

In order to determine the nature of the prostigmin reaction whether due to destruction or to inhibition of the esterase experiments devised by Matthes (1930) on the action of eserine were repeated. Serum taken 10 mins after a therapeutic dose of prostigmin and also a mixture prepared by adding prostigmin in the concentration 10^{-6} to normal serum were dialysed against isotonic saline for 24 hours and the esterase activity of these solutions was then compared with that of undialysed controls and of normal serum The concentration of 10^{-6} was selected as being approximately equal to that present in the serum of the patient on the assumption that a dose of 3 mg of prostigmin was completely absorbed by 3000 c cm of plasma In a typical series of experiments the figures in Table V were obtained

TABLE V

Restoration of Esterase Activity after Removal of Prostigmin by Dialysis

—	Esterase activity		
	Case 1	Case 2	Case 3
1 Normal serum	[illegible]	2·1	3·0
2 Serum after therapeutic dose of prostigmin	1·3	0·8	2·3
3 Normal serum with added prostigmin (1 10⁻⁶)	0·7	0·5	1·2
4 Serum (2) dialysed	2·0	1·8	[illegible]
5 Serum (3) dialysed	2·1	1·6	[illegible]

Thus the depression in esterase activity on the addition of prostigmin in the concentration of 10^{-6} is of the same order as that occurring after a therapeutic dose while its effect on the destructive agent is in the nature of a simple inhibition since on removal of prostigmin by dialysis the activity of the esterase is restored almost to normal

Specimens of urine from 12 patients were tested for esterase activity and in no case was any found Nor did the urine from 2 cases of myasthenia gravis contain any substance inhibitory to esterase activity Two hours after a therapeutic dose of prostigmin, however, urine from these patients was found to possess a strongly depressant effect upon serum esterase, thus suggesting excretion of the drug in the urine

DISCUSSION

These experiments confirm previous observations of the wide variations that occur in the choline esterase activity of different sera, some specimens in the present series showing six times the activity of others In the great majority the values determined remained constant within comparatively narrow limits for each individual patient, while in the few cases in which gradual changes did occur no correlation with other factors could be discovered In myasthenia gravis the serum esterase activity also falls within the normal range, and, as in other diseases, also shows wide variations from case to case with a comparatively constant level for each individual patient The absolute level of serum esterase activity thus appears to bear no relationship with any disease process or with the age, sex, or other physical characteristics of the patient

In the non myasthenic individual there appears to be a state of equilibrium between the rate of liberation of acetylcholine at the motor end plates and the rate of its destruction by the esterase locally present, these factors being so related that the acetylcholine liberated by each nerve impulse can just produce its effect before hydrolysis occurs In myasthenia gravis this normal relationship no longer exists, the failure of the nerve impulse to stimulate the muscle being due either to excessive concentration of esterase at the motor end plates or to deficient acetylcholine production at the same site Since, however, there is no proof that the esterase activity of the plasma, as determined by biochemical estimation, is a measure of its concentration at the motor end plates, no conclusions can be drawn from the present work as to the direction in which the fault lies Brown, Dale, and Feldberg (1936) have stressed the importance of the local concentration of acetyl choline at the motor end plates, and similarly the concentration of the esterase at this site is the important factor rather than its concentration in the plasma Unfortunately no method is at present available by which absolute determinations of esterase activity at this vital point can be made

It has been shown, however, that prostigmin, like eserine, inhibits acetylcholine esterase in vivo or in vitro even in extremely high dilution This inhibition is reversible, since on removal of prostigmin by dialysis, both from the patient's serum after a therapeutic injection and from an artificial mixture of prostigmin and esterase, the activity of the latter is restored In myasthenia gravis there is a close correlation between the degree of depression of the esterase activity of the plasma and the physical condition of the patient, the period of recovery following prostigmin administration coinciding with that of esterase inhibition, while relapse occurs after 4–5 hours as the esterase value is returning to normal At this time also, and at no other, an esterase inhibiting factor—presumably prostigmin in process of excretion—can be detected in the urine During the period of recovery, therefore, the presence of prostigmin in the plasma depresses the esterase activity, both at the motor end plates of the muscles and in the plasma, and so, by re establishing the balance at the former site, restores neuromuscular efficiency This is further supported by the observation that the dose of prostigmin which raises the myasthenic patient to a normal level of activity produces in the non myasthenic subject vigorous tonic contractions of the muscles of the skeletal and visceral systems, due presumably to prolonged stimulation by acetylcholine on artificial depression of the esterase

Russell and Stedman (1936) have recently shown also that the administration of prostigmin to patients suffering from myotonia congenita produces a pronounced increase in muscle tone, and suggest that this condition is due to excessive production or accumulation of acetylcholine at the motor nerve endings It is of interest to note, therefore, that approximately parallel results have been obtained by these workers on the administration of 1 25 mg. of prostigmin to myotonic patients, and by myself on administration of just double this dose to normal subjects

SUMMARY

The esterase activity of the sera of 132 patients, including 3 cases of myasthenia gravis, has been studied Although wide variations occurred no correlation with type of disease or with other factors could be determined

After the administration of prostigmin there is a sudden drop in serum esterase activity This lasts for 4–6 hours, and coincides in myasthenia gravis with the period of temporary recovery of strength. In non-myasthenic subjects a dose of 2 5 mg of prostigmin produces tonic contraction of skeletal and visceral muscles, due presumably to prolonged stimulation by acetylcholine on artificial depression of the esterase

Depression of serum esterase activity by prostigmin is due to inhibition, not destruction, of the esterase, since activity is restored on removal of prostigmin by dialysis

Myasthenia gravis is associated with a failure in equilibrium between the rate of liberation of acetyl choline at the motor end plates and the rate of its destruction by the esterase locally present There is, however, no proof that the esterase activity of the serum is a measure of the concentration of esterase at the motor end plates, a factor which at present cannot be measured

I wish to express my gratitude to Prof F R Fraser, at whose instigation this work was carried out, for his continued interest and encouragement I also wish to thank Sir Henry Dale for valuable criticism and suggestions, and Dr E H. King for advice and assistance with the biochemical estimation of the esterase

CARCINOMA OF THE CERVICAL ŒSOPHAGUS

By Robin Pilcher, M.S Lond F R C S Eng
FIRST ASSISTANT IN THE SURGICAL UNIT UNIVERSITY COLLEGE HOSPITAL, LONDON

The treatment of cancer of the thoracic part of the œsophagus although occasionally coming within the reach of exceptional skill and good fortune remains essentially an unsolved problem The surgical excision of cancer of the cervical part is on the other hand a problem of which the technical solution has been worked out for many years The hope of cure which this solution offered does not, however appear to have been fulfilled and it seems that surgery to day is doing no better for the cervical than the thoracic cases of œsophageal cancer The object of this article is to examine this anomaly and to put forward certain considerations that may perhaps tend to correct it.

Incidence

Carcinoma of the cervical œsophagus is a common disease. The œsophagus is stated to be the seat of one out of every twenty cancers It is generally recognised that the growths are not uniform in distribution but show a definite grouping whereby the upper end the middle part and the lower end are almost exclusively affected. In Lawrence Abel s monograph (1929) a collection of figures from various authors gives the relative frequency in these three situations the averages being upper end 18 per cent. middle part 47 per cent. and lower end 35 per cent In Abel s own cases the upper end was affected in 20 per cent More recently McGibbon (1930) has published observations on 100 personal cases of which 22 per cent. affected the upper end. In these figures post cricoid carcinoma of the pharynx is not included otherwise the percentage would be much larger Thus about one in every five cases of cancer of the œsophagus affects the upper part Though it is difficult to be precise in such estimates it seems probable that about one in every hundred cases of cancer of all kinds affects the upper part of the œsophagus This relatively high incidence is the more impressive when we remember that the disease is technically operable but very infrequently subjected to operation

Special Features

The infrequency with which cancer of the cervical œsophagus has been treated by radical excision has no doubt been mostly due to the infrequency with which an exact and early diagnosis has been possible At present also the possibility of the less exacting though comparatively unproved treatment of radiotherapy doubtless influences against the use of surgical excision Both methods, however suffer almost equally from the fact that the peculiarities of the disease in this situation have not generally received the close attention on which alone any hope of a reasonably early diagnosis can be based Its evolution differs from that of cancer of the thoracic part in certain particulars which seem to be related to its place of origin The normal features which influence the course of the disease are the large diameter of the cervical œsophagus its close application to the trachea the intimate fixation of the two tubes at the cricoid and the enclosure of the œsophagus in the visceral *compartment* of the cervical fascia together with the trachea the recurrent nerves, and the thyroid gland

DYSPHAGIA

Disturbance of swallowing is generally regarded as the cardinal symptom of all growths of the gullet This view while perfectly correct for cancer in the middle and lower segments and in the post cricoid pharynx needs some qualification in the upper segment. Here, while dysphagia always appears sooner or later it may be wholly absent in the early stages and even when structures outside the œsophagus, such as the recurrent nerve already show involvement. The reasons for the not uncommon delay in the onset of dysphagia seem to be first the large diameter of the cervical œsophagus and secondly the nearness of the pharynx with its strong propulsive action

INVOLVEMENT OF ADJACENT STRUCTURES

The anatomical facts already named, especially the enclosure of the œsophagus in the visceral compartment of the neck, render the involvement of adjacent parts peculiarly characteristic of cancer of this part The recurrent nerves the thyroid gland and the trachea are exposed to implication, and sooner or later they are always affected

The *recurrent laryngeal nerves* are the most important since involvement of one of them is often very early and also because this does not necessarily imply that radical excision is no longer possible In the small series of cases reported below to illustrate the theses put forward the first shows well the occurrence of laryngeal paralysis as an isolated symptom *I owe to a personal communication the following* rough notes of two cases that illustrate the singular position occupied by recurrent nerve involvement among the symptoms of cervical cancer

The first was that of a middle-aged man a choirmaster by occupation. While he supposed himself to be in perfect health his voice suddenly failed him as he was taking a class. He was never able to sing again but his loss of voice was unexplained until some months later he developed an œsophago tracheal fistula

The second was that of a man of about 60 who was engaged in politics and did much public speaking He complained that he felt he could no longer depend on his voice No evidence of laryngeal paralysis was found the condition was supposed to be the effect of a neurosis and the patient was sent on a voyage When he returned one vocal cord was paralysed and an enlarged gland was found in the posterior triangle which showed the structure of squamous carcinoma.

The clinician is not infrequently presented with an unexplained paralysis of a vocal cord in a middle aged man He should remember that in such circumstances he is sometimes being given the chance to cure a case of carcinoma of the œsophagus

Involvement of the *thyroid gland* is less common as an early symptom although I have found one case in which it was apparently the first thing noticed amiss by the patient. Its importance lies rather in the confusion that may arise as to the site of the primary tumour In any case with signs of a malignant tumour of the thyroid the possibility of extension from a carcinoma of the œsophagus should be remembered especially if any surgery is contemplated. As with the recurrent nerves involvement of the thyroid gland does not necessarily preclude radical excision

Involvement of the *trachea* is probably the next commonest complication after recurrent nerve paralysis but whereas the latter is not necessarily a sinister sign the *former* almost invariably results in fistula formation and a rapid death from pulmonary infection Perforation of the trachea may be followed by the sudden development of dysphagia for fluids only, but as has been pointed out by McGibbon (1936), who has described non-perforating lesions of the trachea seen by endoscopy, it is preceded by symptoms of tracheal irritation Case 3 illustrates these points The presence of a fistula makes the case practically hopeless for surgical treatment, but a non perforating lesion of the trachea should not prove an insuperable obstacle, although as yet no satisfactory reconstruction of the trachea has been devised

Glandular metastases —In spite of its tendency to involve structures outside the gullet the disease shows no special tendency to affect lymph glands The possibility of metastases is however always present, and cases occur from time to time in which they dominate the clinical picture When the recurrent nerves are involved it is important to consider the possibility of involvement from mediastinal glands rather than from the primary tumour Metastases in the cervical glands, if not extensive, lend themselves to removal as part of a radical operation

Diagnosis

Without specialised methods of examination the diagnosis is usually impossible in the early stages of the disease Early symptoms are trivial, and the responsibility of deciding that investigation is necessary and insisting that it be carried out will rest with the doctor whom the patient first consults If he is assured that his symptoms are due to nothing serious he may not seek advice again until his condition is hopeless The symptoms that are likely to be thus lightly dismissed are weakness of the voice and slight disturbance of swallowing, and although these may be due to a variety of causes any patient in whom they are persistent or recurrent and unexplained should be suspected of malignant disease of the gullet An essential part of the examination is indirect laryngoscopy, a method with which every clinician should be familiar It requires no great skill to detect weakness or paralysis of the arytenoids or swelling of their mucosa, and a view of the larynx itself is often unnecessary If gross abnormality is found on indirect laryngoscopy no hesitation will be felt in ordering a further examination such as radiography or œsophagoscopy, no matter how slight the symptoms In some of the conditions other than cancer of the œsophagus that may give rise to the symptoms mentioned, laryngoscopy alone may establish the diagnosis When laryngoscopy fails to reveal anything abnormal further investigation is essential if the symptoms persist The patient should next undergo an X ray examination, which must of course include screening In spite of great improvements in technique radiography alone may fail to demonstrate an early growth, as happened in Case 1 described below Such a case should always be examined with the œsophagoscope Chevalier Jackson (1934) states that any persistent abnormal sensation or disturbance of function of the œsophagus calls for œsophagoscopy This is an expert's counsel of perfection, but it is doubtful if any progress towards early diagnosis will be made until this method of examination is much more common. Radiography, in addition to revealing the presence of a tumour, may give some indication of its size In lateral films of the neck the outline of the trachea shows a characteristic forward displacement if the œsophageal tumour is at all bulky (Fig 1) This displacement can sometimes be detected clinically, and may produce a partial obliteration of the suprasternal hollow

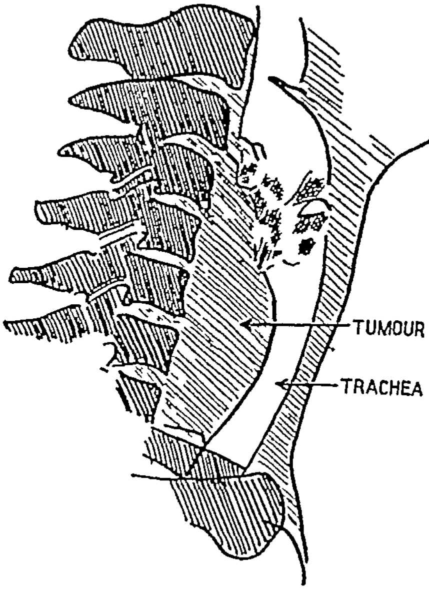

FIG 1 —Tracing of lateral X ray of neck showing displacement of trachea by tumour of œsophagus From a case of post cricoid carcinoma of the pharynx extending down the œsophagus

Surgical Excision

It is not my purpose to discuss the relative merits of different treatments for this disease, but simply

5

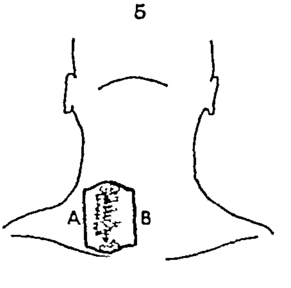

FIG 2 —Incision for cervical œsophagectomy outlining skin flap

FIG 3 —Skin flap passed under mobilised segment of œsophagus containing growth and sutured along original incision This procedure minimises infection of the neck but is only suitable for small growths. In most cases the affected segment must be excised at this stage

FIG 4 —The segment of œsophagus containing the growth has been excised The œsophagus opens above and below on to a trough of skin formed by the flap

FIG 5.—Incision for plastic operation replacing missing segment of œsophagus by a skin tube See also Fig 8

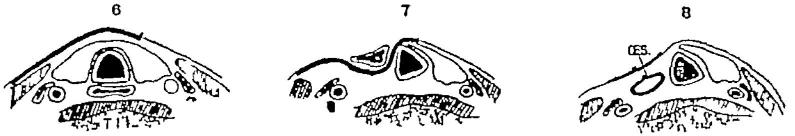

FIG 6.—Diagram of transverse section of neck at level of first thoracic vertebra Skin flap indicated by heavy line

FIG. 7 —The skin flap has been passed under the mobilised segment of œsophagus containing the growth The left lobe of the thyroid gland has been resected

FIG. 8.—The œsophagus has been reconstituted by skin flaps turned in to form a tube (ŒS) The skin has been closed over the tube

to state and show by an example that it is curable by excision That the operation may be difficult and dangerous cannot be denied but these considerations do not deter surgeons from attempting excision of malignant disease in other parts of the body The essential feature of the operation is the excision of the neoplasm with a margin of healthy tissue the amount to be removed cannot be determined until the œsophagus has been exposed and possibly opened It follows that no fully defined plan can be formed beforehand of the steps of the operation but the first incision should outline a generous skin flap which can be used for the plastic procedure that will almost always be necessary Reconstruction of the gullet with skin is a simple procedure but as yet no satisfactory reconstruction of the trachea has been devised If the trachea is removed with the growth the patient may have to be left with a permanent tracheocutaneous fistula in the suprasternal hollow The routine excision of the larynx and upper part of the trachea with the growth as recommended by Carl Eggers (1936) is not necessary and would inflict an unjustifiable mutilation in early cases It may not be possible to decide without exploration whether or not a growth can be excised but involvement of structures outside the œsophagus and metastases in the cervical lymph glands do not necessarily render a case inoperable An essential preliminary to the operation is the elimination of oral sepsis, and all teeth should be extracted.

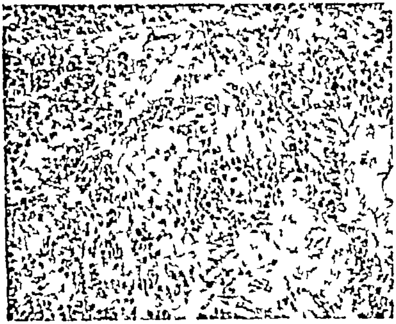

FIG 9 (Case 1) —Carcinoma of cervical œsophagus excised by radical operation (× 85)

Through the kindness of Mr Cecil Joll an opportunity was recently afforded to examine the œsophagus of a man from whom a carcinoma was excised ten years ago In Fig 10 the œsophagus is shown opened posteriorly It is still deviated to the right the side from which the operation was performed. The transition from skin tube to normal œsophagus is barely perceptible although when first opened it was easier to recognise several hairs being found growing from the skin segment This patient was recently admitted to the Royal Cancer Hospital with recurrent chordoma of the sacrum of which he died No evidence was found at post-mortem of any recurrence or metastases of the carcinoma of the œsophagus. The case is reported briefly below and the operative procedure employed is illustrated in the diagrams in Figs 2-8

Case Reports

HOARSENESS THE INITIAL SYMPTOM

CASE 1 —A male aged 61 was admitted complaining of hoarseness for 3 months and dysphagia for 10 days He was found to have enlarged glands in both supraclavicular regions and paralysis of the right vocal cord. Some forward displacement of the trachea was observed Radiography failed to reveal any neoplasm of the œsophagus A gland was removed and showed on section squamous carcinoma. External irradiation of the neck was given without any definite diagnosis having been made Two months later radiography showed obstruction of the œsophagus and a diagnosis of carcinoma was made

Interstitial irradiation was given, but two months later the patient died of hæmorrhage from the right common carotid artery Post mortem an extensive growth was found in the cervical œsophagus, with metastases in the cervical glands and left lung

INVOLVEMENT OF THYROID GLAND

CASE 2—A male aged 68 was admitted complaining of dysphagia for 10 months and a pain in the left side of the neck and shoulder of recent origin His voice had become hoarse during the last month He also complained of a lump in the left side of his neck, and this was apparently the first thing he had noticed wrong He had been admitted to another hospital when the lump appeared but whether its significance was appreciated is not recorded He was found on examination to be wasted, and there was a hard mass above the inner end of the left clavicle involving the left lobe of the thyroid and infiltrating surrounding structures There was paralysis of the left vocal cord and of the left cervical sympathetic This case was advanced when admitted, but there seems little doubt that invasion of the thyroid was an early feature A gastrostomy was performed and gave the patient temporary relief

ŒSOPHAGO TRACHEAL FISTULA

CASE 3—A female aged 52 was admitted complaining of inability to swallow liquids for 3 weeks, although solids passed without difficulty Ten weeks before admission she had an attack of bronchitis lasting 2 weeks, after which she had a persistent cough with occasional hæmoptysis Pulmonary tuberculosis had been suspected and the sputum was examined with negative result There had been rapid loss of weight since the onset of the dysphagia By œsophagoscopy a growth was seen in the upper part of the œsophagus, with a small perforation into the trachea During the endoscopy an emergency tracheotomy became necessary, but the patient only survived a few days

CURE BY RADICAL EXCISION

CASE 4—A male aged 62 was admitted on June 23rd, 1925 complaining of difficulty in swallowing for 6 months and hoarseness for 2 months No tumour was palpable in the neck and neither vocal cord was paralysed, but the right moved more freely than the left Carcinoma of the cervical œsophagus was found by œsophagoscopy and was later confirmed by histological examination (Fig 9) After preliminary gastrostomy and extraction of teeth excision of the growth and reconstruction of the œsophagus were carried out by Mr Wilfred Trotter as follows —

nom
its

The symptoms of the disease are described, emphasis being laid on the tendency to involvement of adjacent parts, especially the recurrent laryngeal nerves

Special methods of examination are necessary to establish an early diagnosis A plea is made for the more frequent use of the œsophagoscope in suspicious cases.

The disease is curable by surgical excision

Four illustrative cases are briefly reported, including an example of surgical cure

I am indebted to members of the staff of University College Hospital for permission to make use of their cases in this paper

PERNICIOUS ANÆMIA AFTER NITRIC ACID CORROSION OF THE STOMACH

BY G ALSTED, M D Copenhagen

ASSISTANT PHYSICIAN TO THE MEDICAL DEPARTMENT B OF BISPEBJERG HOSPITAL COPENHAGEN

KNOWLEDGE of the pathogenic importance of the stomach, or more correctly, of the gastric mucosa, in various anæmic conditions is of no recent date. As early as 1877 Fenwick pointed out the atrophy of the mucous membrane of the stomach in pernicious anæmia, and this, manifesting itself as achylia, was soon directly connected with the development of pernicious anæmia But it is not only in pernicious anæmia that the function of the gastric mucosa has turned out to be important Faber conceived the notion of simple achylic anæmia, and showed in a large number of cases the close relation between achylia and simple hypochromic anæmia Furthermore, several investigations have been reported showing that hypochromic anæmia often occurs after gastric operations, especially after gastrectomy

While the relation between gastric function and anæmia was thus established rather early, several years passed before a more profound knowledge and understanding of the causative mechanism developed. In pernicious anæmia it was the discovery of the favourable effect of liver therapy that provoked a new interpretation of its pathogenesis, and on the basis of work by Castle and his co workers, and more recently by Meulengracht and his co workers results have been achieved that bring about a certain knowledge of the factor whose deficiency causes the anæmia Its place of origin—the pyloric glands and the Brunner glands in the duodenum—also seems to be fixed This agrees perfectly with records of pernicious anæmia developing after resection of the stomach, Goldhamer having collected 23 cases from these reports These anæmias may in a way be regarded as experimental cases of pernicious anæmia When, as it appears from various control post operative examinations of patients, pernicious anæmia seems only exceptionally to follow gastric resection, it is undoubtedly due to quantitative conditions, since generally it may be assumed that, in spite of operation, sufficient glandular tissue is left to prevent the development of pernicious anæmia

CLINICAL REPORT

Special interest is presented by a case of pernicious anæmia, recently observed in the Medical Department

B of Bispebjerg Hospital, which seems to have developed as a direct consequence of corrosion of the gastric mucosa by nitric acid In 1932 Fleischer Hansen recorded the same case but mainly from a surgical point of view the following communication from the medical angle is made because of the further development of the case since Fleischer Hansen s article No similar case seems to have been recorded

The patient is a woman, now 43 years of age. On Sept 19th, 1035 she was admitted to the Bispebjerg Hospital suffering from pernicious anæmia She had *once before (December 1031) been admitted to the hospital* The history of her disease is a lengthy one comprising several admissions to various hospitals, all on account of her present condition The details of the first part of the *anamnesis are furnished partly by the patient* herself partly by the Horsens City Hospital and partly by Fleischer Hansen s paper

Briefly there is nothing of interest concerning her present disease until June 22nd 1921 when the patient having for some time shown signs of a manic-depressive psychosis in an excess of depression attempted to commit suicide by drinking half a cup of nitric acid The following day she was admitted to Horsens City Hospital where the corrosion was recognised. She quickly improved though she suffered for a time from frequent vomiting During her stay in hospital no evidence was found of any stricture the general condition as mentioned improved quickly the vomiting decreased the hæmoglobin was 88 per cent (Sahli) There was no difficulty in swallowing *either at that time or at any other during the course of* the disease

In the following years the patient again had gastric attacks mainly of vomiting those being so violent that *she at last retained practically no food She consequently* became extremely emaciated and—what is of considerable interest—grew first slightly then more severely and finally exceedingly anæmic *Several Ewald test-meals* showed *complete* gastric achylia As early as November 1021—i.e five months after the corrosion—the hæmoglobin only amounted to 60 per cent After this the hæmoglobin percentage *is known to have been decreasing* steadily until a hæmatological examination made on Oct 4th, 1028 showed these results :

Hæmoglobin	2 per cent	White cells	1880
Red cells	1,000 000	Icteric-index (Meulengracht)	9
Colour-index	1 1		

The blood smear showed distinct anisocytosis and megalocytosis The weight at that time was 37 kg

The general condition of the patient had thus become quite serious and an X ray examination performed with much difficulty showed the gastric lumen to be reduced to an orange sized space in the fundus evacuation into the duodenum taking place *through a canal about 10 cm.* in length and with a width hardly that of a pencil A gastro-enterostomy was performed on Feb 13th 1029 At the operation the radiographic finding was verified the stomach having been converted into a small sausage shaped organ with the calibre of a normal colon The pyloric part showed walls 1 cm thick and the gastric mucosa seemed to be totally deficient The duodenum was surrounded by numerous adhesions, but was otherwise normal A small piece from the fundus was excised for microscopic examination and here the mucosa, the submucosa and part of the muscularis were completely transformed into fibrous tissue few remnants of the glands being found There was no sign of malignancy

After the operation which the patient *supported* amazingly well she improved considerably the signs of pyloric obstruction subsiding A disposition to vomit continued the patient only being able to eat small meals ; furthermore there was frequent diarrhœa interpreted as gastrogenic in type She remained however extremely anæmic, and an examination of the blood made in July 10 9 *five months after the operation showed this result :*

Hb	20 per cent.	White cell	2160
Red cell	850 000	Icteric index	11
Colour-index	1 19		

The blood smear showed megalocytosis with an average diameter of the red cells of 9 3 μ, with a few megaloblasts. She was treated with blood transfusions and extracts of liver and stomach the treatment however suffered much from her bad mental condition which often led to a *refusal to eat*

A month later August 1020 the hæmoglobin had decreased to 17 per cent and the red cells to 800 000 but her psychosis now subsided and, treatment thus *becoming effective* the hæmoglobin percentage quickly increased During a later stay in the Horsens City Hospital in May 1931 her weight was 55 kg and an examination of the blood gave the following results :

Hb	83 per cent.	White cells	5200
Red cells	5 400,000	Icteric index	5
Colour-index	0 83		

At that time no reticulocytes were counted

At the end of 1930 the patient had begun to suffer from a disturbed gait to which were added acroparæsthesiæ, numbness of fingers and toes and soreness of the tongue During the last mentioned admission, a slight spastic paralysis of the lower extremities had been found with a positive Babinski s sign, and increased deep reflexes together with slight clonus. It remains to be noted that the patient as early as 1025 suffered from a tendency to blisters " on the tongue

In spite of the improvement of her anæmia her condition remained poor the patient being much troubled by spinal symptoms and not being able to attend to her work at home She also suffered from extreme fatigue and she was *admitted in December 1931 into the* Bispebjerg Hospital to be observed before being awarded invalid benefit She was now found to be in an alternating psychosis condition highly stamped by her mental disorder *The weight was 52 kg and Wassermann reaction* was negative No signs of corrosion were found The tongue was smooth and glistening with atrophy of the papillæ On examination of the lower extremities the *power was found unimpaired the deep reflexes were* spastic and there was slight ankle-clonus Babinski's reflex was positive on the right side Ataxia was found in the knee-heel test. Sensibility was normal the gait was unsteady but not characteristically spastic A hæmatological examination showed :—

Hb	50 per cent	White cells	3300
Red cells	4,040,000	Icteric index	5
Colour-index	0 75		

A differential count gave *normal* figures In the urine no pathological elements were found An X ray examination of the œsophagus and the stomach showed no pathological changes in the œsophagus The stomach had the appearance and the width of intestine the pyloric part and the duodenal bulb could not be recognised (Fig 1)

During her stay in the department the patient was allowed up ; she felt constantly hungry but did not suffer from dyspepsia apart from slight oppression after meals When the patient was discharged her weight was 53 kg

As mentioned the mental condition of the patient was very variable and in August 1032 she made a less serious attempt at suicide and was consequently admitted into the psychiatric department of the City Hospital at Copenhagen. During the stay her nervous lesions were found *to be unchanged and the hæmoglobin percentages were* as follows August 17th 55 ; Sept 10th 50 Sept 21st 60 ; Oct 13th, 68 She was treated with extract of liver and Ventriculin and her weight increased by 2 3 kg in spite of frequent diarrhœa

After her discharge the patient was treated at the hospital s medical out patients clinic with various preparations of liver and stomach, several of which had no effect It seems likely that she periodically neglected treatment but we have not obtained sure evidence of this Her condition however was growing constantly worse and *immediately before her admission to the* Bispebjerg on Sept 19th, 1935 she had been lying in bed in her home for at least three months without any treatment at all.

On *admission therefore* the patient was extremely exhausted slightly confused subicteric. Extreme anæmia was present together with symptoms of heart failure venous stasis in the organs and pronounced œdema The spinal lesions seem to have remained stationary the condition being found practically unchanged from the previous admission four years before Treatment was begun at once, she was given Pylorin* together with extract of liver but in spite of this her condition grew worse The temperature was rising, indicating an infection of the urinary tract with colon bacilli, and it was found necessary to perform a blood transfusion After this the patient improved the temperature fell, the vomiting ceased, and she took her medicine without any difficulty The œdema and the stasis disappeared, her mental condition improved, and she has since presented nothing abnormal in her psychotic condition The blood examinations appear in the accompanying Table In Fig 2 the various counts are plotted graphically

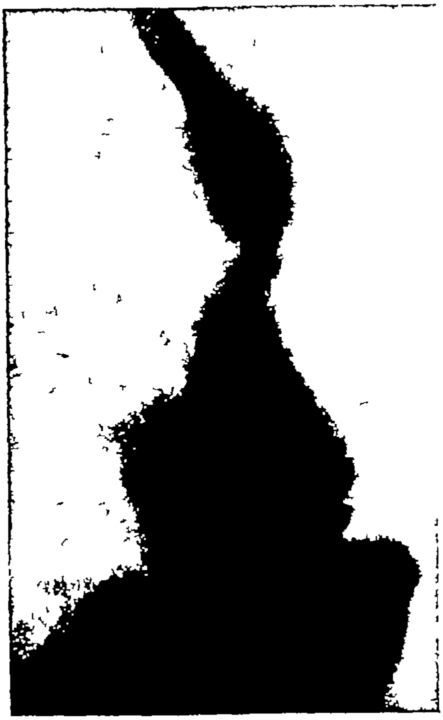

FIG 1.—Radiogram of the œsophagus and the stomach The pyloric part and the duodenal bulb are unrecognisable

The blood smear from Sept 25th showed a lymphocytosis of 72 per cent , some megalocytes but no other abnormalities The remaining examinations such as Wassermann reaction and electrocardiography gave normal results An X ray examination of the stomach showed the condition unchanged from the previous examination four years before , a rapid passage through the gastro-enterostomy was seen but there was no evidence of intestinal stricture

The experiences from the previous admission being kept in mind a Ewald test meal was not attempted but a fractional gastric analysis was performed no fasting secretion was obtained, but after a histamine injection 2–13 c cm of gastric content was aspirated It was of a slightly yellow colour not reacting to Congo red paper , the acidity, titrated with phenol phthalein as an indicator, amounted to from 6 to 10 The slight yellow colour might suggest regurgitation through the anastomosis, but it is doubtful if this could be avoided

As apparent from the Table and the graph a rapid rise in hæmoglobin and especially in the red cells began in direct connexion with the blood transfusion At the same time the general condition improved as already mentioned, so that the patient in the course of a short time was able to move out of bed The high reticulocyte counts at the beginning are peculiar , it seems doubtful if they are caused by the treatment with preparations of stomach and liver, prescribed only two days before. It might be suggested that the patient, when admitted, was in a state of spontaneous remission

In spite of the improvement of the blood counts and of the general condition of the patient, her weight during a long time showed a constant and regular decrease for a while being far below the weight at the previous admission Compared to the ravenous appetite of the patient, this constant loss of weight seemed most remarkable Periodically she ate up to 40 sandwiches in a single meal without any notable dyspeptic trouble, an astonishing fact considering the small capacity of her stomach. Part of the loss of weight is undoubtedly due to the disappearance of the œdema, but all of it can hardly be explained in this way At the same time her stools being at first watery, became solid and very voluminous, the weight amounting to 400 grammes Since it was not fatty diarrhœa, presumably the quantity of fæces was due to an extremely bad absorption of food, caused by the hasty passage through the anastomosis into the jejunum The greater part of the food thus passed unabsorbed through the digestive tract, this explains the disproportion between the abundant intake of food and the weight of the patient This, however, turned out to be only a transitory phenomenon , shortly afterwards her weight began increasing and at the time of discharge, on Nov 24th, her weight was 51 3 kg —i e , she had put on 9 kg in weight At the same time the hæmoglobin had risen to 74 per cent , and the patient was discharged from the hospital, being told to continue the combined treatment with pylorin and extract of liver A control examination two weeks later showed that her weight had increased a further 5 kg , the hæmoglobin percentage had remained stationary, the red cells having, however, risen to normal She gave then the impression of an absolutely normal woman, her appetite still being extensive, even if not as ravenous as before , she suffered from no dyspepsia, and her stools were normal in all respects Of her former complaints, only the irreparable spinal symptoms remained

DISCUSSION

No doubt is likely to be raised about the diagnosis that this patient was suffering from pernicious anæmia, and it seems to be most probable that her disease developed as a consequence of the corrosion of her gastric mucosa, this being, as observed at the operation, completely destroyed, especially in the pyloric portion Three months after the injury her hæmoglobin had already fallen to 60 per cent, and the fact that about seven years had to pass before the pernicious anæmia had completely developed coincides with general experience Thus Goldhamer, reviewing the reports on pernicious anæmia resulting from resection of the stomach, found the period

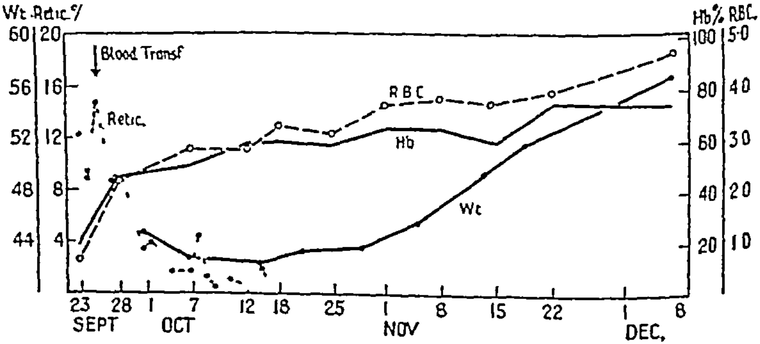

FIG 2.—Showing the patient s progress

---

[*] A preparation made by Medicinal Co Ltd Copenhagen according to the work of Meulengracht exclusively from the pyloric part of the stomach of the pig

of development from 5 months to 15 years Thus the destruction of the pyloric glands, caused by the corrosion in this patient has produced a genuine pernicious anæmia with all of its classical symptoms There is no reason to suppose that there were any other concurrent causes no evidence of intestinal stricture was found as already mentioned

The patient's remaining anæmia after the gastro enterostomy was probably due to the difficulties in achieving a rational therapy because of her mental condition but even later when the giving of treatment was successful, her anæmia seemed to respond somewhat unusually It was evidently being kept compensated only with some difficulty; this is apparent inter alia from the swinging hæmoglobin percentages and from the development of spinal symptoms. I do not think that these circumstances can be completely explained as being due to incompleteness of the treatment since this was very energetic while it was being carried on; neither can it be explained as being caused by the negligence of the patient since it was not of any importance until late in the disease

Treated with pylorin and liver extract from Sept. *1st.
† Blood transfusion 500 c.cm

In my opinion it seems to be likely that her condition, apart from her pernicious anæmia was influenced by the general agastria this being further accentuated by the gastro-enterostomy Her condition also contained elements of a hypochromic anæmia this expressing itself in the difficulty of making the hæmoglobin percentage rise to normal in spite of the combined treatment with pylorin and extract of liver contrasting with the red cell count which as mentioned finally showed normal values As shown by Cosin and Hurst Meulengracht (1934a) Hartfall and Larsen gastro-enterostomy alone may cause anæmia this most frequently being hypochromic and very similar to the simple achylic or achlorhydric anæmia In most of the observed cases achylia and a quick emptying of the stomach through the anastomosis was present In some few cases Hartfall (1934) Larsen (1934) a hyperchromic anæmia developed responding to liver treatment and being very similar to pernicious anæmia.

In this case as mentioned no doubt several factors contributed to create the present not quite typical picture Being treated with preparations of stomach and liver her anæmia has lost the pernicious character she is now left with a gastro-enterostomy anæmia better called an agastric anæmia together with irreparable symptoms as the atrophy of the papillæ of the tongue and the spinal lesions The hasty passage through her anastomosis and the bad absorption of the food combined with it also expressing itself in loss of weight even if only transitory may be supposed to cause the part of her anæmia that turned out to be unaffected by liver and stomach treatment The prognosis of her disease will no doubt be directly dependent on the success of the treatment in combating the conditions described; this needs the patient's active coöperation It looks as if this has succeeded, at least at present and that is why it is permissible to make a fairly favourable prognosis.

The unquestionable connexion between the destruction of the pyloric glands and the development of anæmia makes the case a good example of the importance of the gastric mucosa in the pathogenesis of pernicious anæmia strongly supporting at the same time the theories conceived during latter years.

SUMMARY

A case of typical pernicious anæmia is described developing in a woman, aged 43 in the course of seven years after corrosion of the stomach by nitric acid. This completely destroyed the gastric mucosa especially in the pyloric part the stomach being transformed into a small sausage-shaped organ with intestinal dimensions and with a considerable pyloric stenosis Gastro enterostomy was performed 7½ years after the corrosion connecting the orange sized gastric cavity with the jejunum Treated with preparations of liver and stomach the general condition improved, though it was difficult to keep the anæmia compensated spinal symptoms thus developing

During a recent admission to hospital, however the condition was found to be serious the patient having been untreated for at least three months previously After a blood transfusion and specific treatment the patient improved fairly well, though remaining somewhat anæmic It is supposed that this anæmia now hypochromic is due to the gastro enterostomy and general agastria since it is demonstrated that there is a very quick passage of food through the anastomosis causing extremely bad absorption

PULMONARY FIBROSIS IN CHILDREN

A REPORT ON TWENTY THREE CASES

By M O Raven, D M Oxon, M R C P Lond

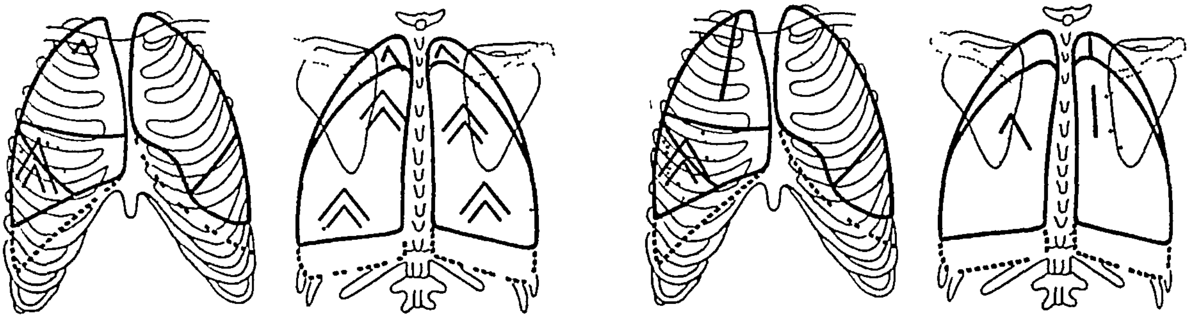
PHYSICIAN TO THE RAMSGATE GENERAL HOSPITAL MEDICAL OFFICER OF THE ST MARY S AND OF THE CLEVEDON CONVALESCENT HOMES BROADSTAIRS

Having had 45 children with pulmonary fibrosis under my care at Broadstairs between June, 1928, and August, 1934, it seemed worth while inquiring into the subsequent histories of some of them Excluding a number of mild and more recent cases, 29 children were chosen for circularisation and as a result 23 were traced by the efforts of the Invalid Children's Aid Association Of these 16 were re examined at a special clinic, while reports (non medical) were received from another 7 The remaining 6 cases could not be traced. Fortunately, nearly all the cases with most long standing illness and with the severest physical signs were included among those that turned up at the clinic, and the report is largely based on these

RESULTS

No death was reported on the contrary, with one exception, good health and improvement in the local condition were found, though most of the children had been away from time to time to special schools and convalescent homes

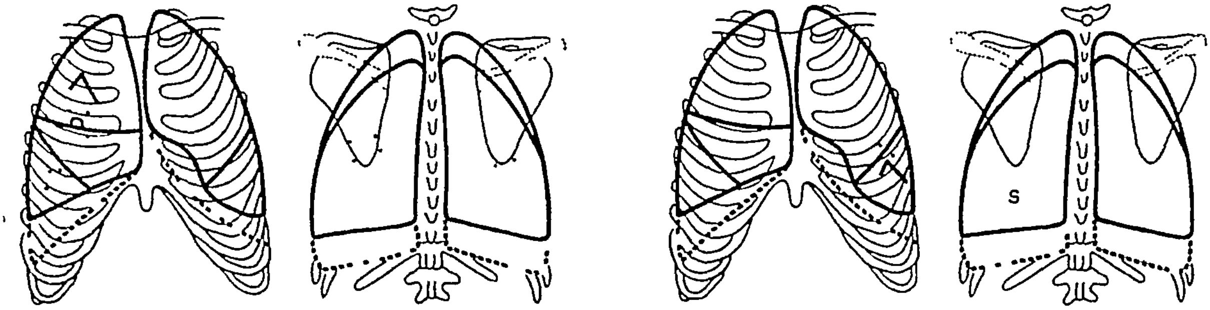
The exception was a girl noted as "very undersized," when she was at Clevedon Home, Broadstairs, in 1931, she then, at the age of 7, weighed 2 st 8½ lb Re examined in December, 1935, at the age of 12, she only weighed 3 st 9 lb and presented very extensive bronchiectatic signs with dislocation of the heart to the extent of 2½ in., she had also severe cough, 4 oz sputum daily, considerable dyspnœa, and clubbing of the fingers, and she had had recent hæmoptysis This was in contrast with her condition in 1931 when she was discharged to London free from symptoms



Case 1 —Girl aged 6½ in January, 1929

1929
Bronchiectasis for 2 years previously no symptoms

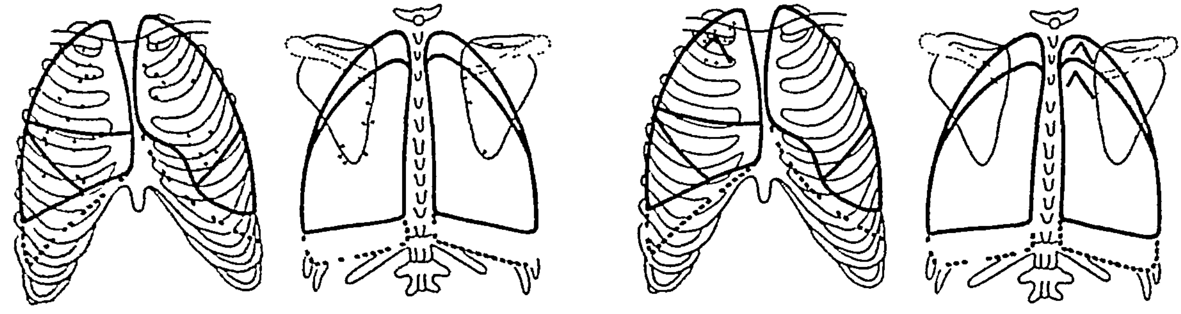
1935
Slight dyspnœa and cough heart pulled over to right progressive fibrosis



Case 2 —Boy aged 6 in January 1929

1929
Chronic bronchitis 2 or 3 years no symptoms

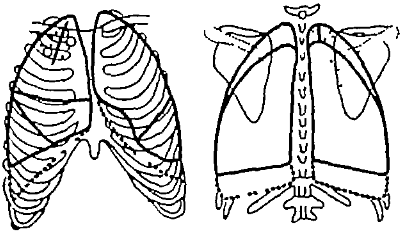
1935
Much improved slight cyanosis and clubbing of fingers mad on football"



Case 3 —Girl aged 7 in October 1928 Fibrosis left lung following on previous pneumonia

1928
Admission to home no symptoms beyond slight clubbing of fingers

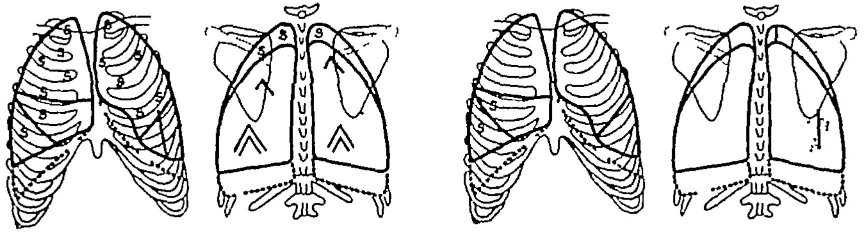
1929
Discharge to London No symptoms



CASE 3 (*continued*)
1935
Played games at ordinary school till last summer no more cough than any one else has There had been a recent bright hæmoptysis Dr M Davidson tells me there is no sign of tuberculous infiltration Sputum showed no tubercle bacilli after the hæmorrhage

With this exception the reports and findings as to general health were favourable One boy, who had extensive signs in both lungs in 1929 was said to be mad on playing football and had greatly improved physical signs A girl discharged in 1929 after 10 months at the sea was reported to be well and working in an office. Other reports in cases showing extensive physical signs in 1930 or earlier were: No sputum and keeping well Done well; no sputum; never ill since leaving the home : Trouble with chest sputum only in winter; getting on well.

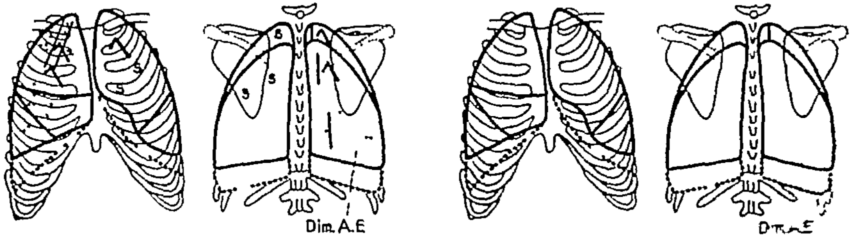
The above reports, taken by themselves are not perhaps, very convincing but it is fair to say that with the exception of the one severe case quoted of the 16 children that came for examination none appeared invalid and most were in robust health—as indeed one usually finds them to be at convalescent homes even when the physical signs are very



CASE 4 —Girl aged 8 in April, 1929

1929
Cough rickettу-shaped pigeon-chest; fibrosis coughing a lot clubbing of fingers

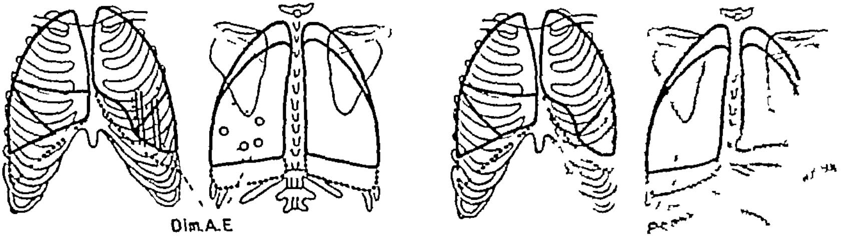
1935
Does office work illness after coming home nothing since; has done well



CASE 5 —Girl aged 7 in December 1929

1929
Pulmonary fibrosis; some cough.

1935
"Never an illness since."



CASE 6.—Girl aged 7 in June 1930

1930
"Fibrosis of lungs", cough; clubbing of fingers.
Dim.A.E. = Diminished air-entry

1935
Cough has [illegible] gradually [illegible]

extensive The signs are hard to summarise, variations being very pronounced, but it may be said that râles show diminution in extent and in number, that, with progressive fibrosis, areas of cavernous breath sounds do not necessarily enlarge, which perhaps accounts for the fact that only in very few cases did the parents report the presence of sputum

CASE REPORTS

It will probably be simplest if I report in detail the progress of six advanced cases (see Charts)

SUMMARY

Of 23 cases of pulmonary fibrosis in childhood, 22 were reported or found on examination to be in good health generally after an interval of from 3 to 6 years None had died. Improvement made at a convalescent home had been maintained and in many cases increased Deterioration in the physical signs was found to be the exception

I should like to thank the Invalid Children's Aid Association for their great assistance in organising the clinic at which the patients were re examined

---

OXYGEN ADMINISTRATION

FURTHER OBSERVATIONS

BY J ARGYLL CAMPBELL, M D , D Sc Edin

(*From the National Institute for Medical Research*)

AT present the common methods of oxygen administration are the closed tent (Hill 1921, Campbell 1934)—a form less frequently used is the open tent or box (Campbell 1934 [1])—and the nasal catheter (Campbell 1934, Marriott and Robson 1936) The disadvantages of the closed tent are the isolation of the patient, the constant skilled attention required for efficient running, and the expense, which usually amounts to 30*s* –40*s* a day The open tent has similar disadvantages, except that the patient is not quite so isolated and gains freer exchanges of air The disadvantages of the nasal catheter are the irritation of the nasal mucous membrane with high rates of oxygen flow for prolonged periods, and the need for local anæsthetics , also the catheter is very wasteful of oxygen, which makes its running expenses as high as those for the tent Because of these disadvantages a box mask (Campbell 1936a) and a small face tent have been introduced, the running expenses of which are about 15*s* a day if 100 c ft cylinders of oxygen are used The face tent is similar in shape and principle to the box mask, but whereas the latter is made of aluminium or cardboard, the former is constructed from wire and closely woven linen For similar efficiency the expense of the box mask or face tent is half that of either the large tent or catheter Also with the mask no analysis of gas is required and there is no obstruction to breathing since there are no valves to be opened and closed Valves constitute the disadvantage of the usual rubber face masks Further the box mask requires a minimum of attention and little skilled knowledge

The large tent makes the whole bed more or less gas tight but the upper part of the body and the head are free inside the tent , isolation is however almost complete With the catheter or box mask the head is not completely enclosed and the patient can communicate freely with others, but for this advantage the patient must put up with some apparatus on the face

THE BOX MASK

The box mask (see Figure) was described in previous communications (Campbell 1936a and 1936b) to which the reader is referred for details When made of aluminium it weighs about 100 g , but it may be improvised from a cardboard box and a catheter in about ten minutes, and if made of thin material is much lighter The aluminium mask is, of course, the more durable but not more efficient. When in use the mask is connected with a Bobbin flow meter (1 in Fig) through which the oxygen passes from a standard automatic regulator fixed to the oxygen supply cylinder It is not necessary to moisten the oxygen, especially as moisture from the expired air condenses on the inside of the mask

Table showing Experiments with Box Mask under Varying Conditions

Date	Condition of subject	Volume breathed, litres per min	O_2 flow, litres per min	Alveolar pressures * per cent atmosphere		Mask used and its conditions
				CO_2	O_2	
1936 May 28th	Sitting resting	7	6	6 1 6 3	50 0 50·0	Aluminium mask without curtain.
Nov 10th	"	7	6	5 6 5 2	46 3 50 6	Linen face-tent moistened without curtain
July 8th	"	7	6	5 9 6 0	66 8 70 3	Aluminium mask with curtain
July 9th	" "	7 7	8 7	5 7 5 6	77·0 70 9	" "
Oct 28th	Exercise	10	6	6 5 6 7	38 8 36 7	Aluminium mask without curtain.
Oct. 27th	"	10	6	6 9 6 8	45 8 42 6	Aluminium mask with curtain

* The alveolar gas samples were taken by the Haldane method immediately after removal of the mask from the face about 5 c.cm were analysed in the large Haldane apparatus

It was shown previously (Campbell 1936a) that it is possible to maintain an oxygen pressure of about 50 per cent of an atmosphere in the lung alveolar air, with an oxygen flow of 6 litres per min (see Table, May 28th) Further observations have now been made, with a similar oxygen flow, to obtain alveolar oxygen pressures higher than 50 per cent This figure is sufficient for all ordinary purposes—e g , in pneumonia—but in cases of carbon monoxide poisoning it is desirable to use almost pure oxygen for short periods to hasten the separation of the carbon monoxide from the hæmoglobin For this purpose a curtain of lint (3 in Fig) is attached, by means of an elastic band, to the lower open end of the mask so that the curtain hangs about 4½ in below the lower end of the mask The curtain must at the same time close the small openings at the lower ends of the sides and front of the mask The curtain is freely open below and hangs collapsed on the chest but, with oxygen flows of 6 litres per minute or more, there is enough ventilation through the collapsed open end to prevent accumulation of carbon dioxide or monoxide

With this arrangement and a flow of 6 l of oxygen per min the alveolar oxygen pressure becomes about 65–70 per cent (see Table, July 8th) while with a flow of 8 l per min. the alveolar oxygen pressure becomes about 80 per cent

---

1.—The front of the box mask with the inlet tube above attached to the Bobbin flow meter which in turn is connected with the automatic regulator on the O cylinder

2.—The wire frame for the linen face-tent the bent inlet tube is seen above The bottle-shaped opening accommodates the nose and mouth

3.—The box mask from the front with the curtain of lint below

(Photograph by L W Collison.)

(July 9th) These figures were obtained with the subject sitting quietly with head slightly bent forward and with a respiratory volume of 7–8 l per min In order to test the mask with a larger respiratory volume e.g 10 l a min —as is observed with some patients with respiratory distress—the subject performed mild exercise to raise his respiratory volume to about 10 l per min He stepped up on to an ordinary chair (18 in high) and stayed there for 30 secs and then stepped down again remaining on the floor for another 30 secs He repeated this routine once a minute for 6–10 mins breathing through the mask all the time With oxygen flow of 6 l per min. into the mask the alveolar oxygen pressure was 37 per cent (Oct 28th) but with the curtain of lint at the bottom the pressure was 45 per cent (Oct 27th) As the movement of exercise changes the position of the mask and curtain these figures must be considered minimal

With a patient in bed the lower open end of the mask is just above and faces the chest while the curtain of lint lies on the chest the curtain retards the exit of oxygen from the mask and at the same time retards the entry of air into the mask so that the oxygen concentration in the mask is raised Without the curtain the lower end of the back of the mask is almost touching the chest with the patient in bed and the head slightly bent forward on the pillow The chest in this case also acts as a slight check on the flow of oxygen out from the mask and the entrance of air into it All the observations with the mask in the resting subject have been made with the head slightly bent forwards as in the patient If the head is held straight up there is freer exchange between the oxygen in the box and the air outside and therefore the alveolar oxygen pressure is slightly lower with the head in this position.

A SMALL COLLAPSIBLE FACE TENT

This face-tent is really a modified box mask It has the same shape and is run on exactly the same principle but it is very much lighter weighing less than 50 g and is thus of value with aged or frail patients It is made of a framework of wire (2 in Fig) covered with closely woven linen The framework is collapsible an advantage where space saving is required in transport Another advantage of this apparatus is that the linen may be moistened with water when the patient is hot or feverish. The evaporation of moisture from the linen will cool the face as well as the gas to be inspired The results for alveolar oxygen pressure with this small face tent, either moistened or dry are similar to those with the box mask Thus a flow of 6 l. of oxygen per min. raises the alveolar oxygen pressure to about 45–50 per cent (see Table Nov 10th)

Leonard Hill (1915) used a similar face covering but the principle is not the same The efficiency of the box mask and face tent depend on the end of the inlet tube (or catheter) for oxygen being bent upwards so that the incoming oxygen strikes the middle of the top of the apparatus

SUMMARY

It is shown how with the aid of a short curtain of lint alveolar oxygen pressures of 70–80 per cent may be obtained with the box mask and a moderate flow of oxygen Such pressures are required in carbon monoxide poisoning or for short periods on other occasions The box mask may be improvised from a light cardboard box and a catheter in ten minutes

A small collapsible face-tent weighing less than 50 g is described for use with frail patients It works on the same principle as the box mask and with a flow of 6 l of oxygen per min raises the alveolar oxygen pressure to about 45–50 per cent

All the apparatus may be obtained from Messrs Siebe Gorman and Co Ltd 187 Westminster Bridge-road S E 1

INTERNAL PNEUMOLYSIS*

A FURTHER ONE HUNDRED CONSECUTIVE OPERATIONS

By F G Chandler M D *Camb* F R C P *Lond*

PHYSICIAN WITH CHARGE OF OUT-PATIENTS ST BARTHOLOMEW'S HOSPITAL SENIOR PHYSICIAN CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS VICTORIA PARK E.

In The Lancet of Oct. 10th 1936 I published the results of 110 consecutive operations The present series follows straight on

The 100 operations were performed during 1934–36 on 68 tuberculous patients As in the first series the cases were unselected in several there was bilateral disease and in some a bilateral pneumothorax Every patient where possible has been followed up at three monthly intervals I would point out however that I am unable to control the after treatment of many of them Not that I have any adverse criticism of this but in some I think I should have left certain effusions alone that were aspirated in others I might have made an oleothorax while in others again I might have made a bilateral pneumothorax

---

* It has been pointed out to me by Dr F R G Heaf and others that the term "pneumolysis" is incorrect and that the word should be "pneumonolysis." At the same time the abbreviation has been established by usage as for example in pneumococcus and pneumokoniosis

There may appear to be a discrepancy in the figures This is because some patients were operated on two or three times, in one case an operation was performed first on the right and then on the left side of the chest

Of the 68 patients the youngest was sixteen and the oldest forty nine The operations and their results are summarised in the accompanying Table

ADHESIONS

(varying from simple bands to complicated systems of adhesions sometimes more than 4 in wide and 2 in or more thick)

	Cases
Single	16
Two to three	19
Four to six	19
More than six	15

TECHNIQUE

	Times
Two instruments	3
One instrument	97
Electrocautery alone	4
Diathermy and electrocautery combined	96

MECHANICAL RESULT

	Cases
Complete collapse	31
Greatly improved collapse	30
Closure of cavity without complete collapse	4
Unsatisfactory collapse	4

PLEURAL EFFUSION SOON AFTER OPERATION

	Cases
Slight (just covering diaphragm)	8
Moderate	2
Much (more than one-third up chest)	2

EFFUSION SOME WEEKS AFTER OPERATION

	Cases
Slight (just covering diaphragm)	12
Moderate	9
Much (more than one third up chest)	4
Obliterative pleurisy	5

SURGICAL EMPHYSEMA

	Times
Slight	27
Moderate	4
Much	4

FEBRILE REACTION

	Times
None	61
Evanescent	31
More than three days	5
More than six days	3

EMPYEMA

One case Tuberculous empyema occurring four months after operation

HÆMORRHAGE

Oozing occurred in one case easily controlled by diathermy

PRESENT CONDITION

In good health (no tubercle bacilli in sputum)	46
In fair health	11
Relapse or extension to other side	7
Very ill	3
Dead	1
Untraced	0

As there has been controversy about the use of diathermy, I would make it clear, as in the previous article, that I abandoned using the cutting current after Operation No 50 in the first series, but I have almost always used the coagulating diathermy current for coagulation before burning, except in obviously avascular adhesions

There is no doubt that often the diathermy coagulating current is unnecessary, but it is a safe guard Coagulation is required for the control of brisk oozing, and for comfort and ease of operating it is highly desirable to be working in a dry, white field, and not in one partially obscured by blood, whether coagulated or not These conditions are more likely to be obtained by the use of diathermy

Finally, I think most workers would agree that for enucleating adhesions diathermy for coagulation is essential My own practice is to enucleate only when necessary

Clinical and Laboratory Notes

DIVERTICULITIS WITH AN UNUSUAL TERMINATION PYLEPHLEBITIS SIMULATING WEIL'S DISEASE

By W T Cooke, M B Camb, M R C P Lond.

LATE HOUSE PHYSICIAN THE ROYAL HOSPITAL WOLVERHAMPTON

The signs and symptoms of diverticulitis are very varied They may be those of generalised peritonitis acute or chronic "left sided appendicitis," pelvic abscess, acute or chronic obstruction, or carcinoma of the colon, or they may be those of general ill health and vague abdominal pains The case described below had none of these text-book symptoms and the correct diagnosis was only made in the post mortem room

The patient a man aged 34, was admitted to the Royal Hospital, Wolverhampton, on March 1st 1936, with jaundice and pyrexia Seventeen days previously he had been taken ill with shivering attacks, generalised aches and pains, nausea, and slight vomiting He had had some pain in his epigastrium but he was very vague about its character and localisation. He could not remember the exact day when he became jaundiced. He had no itching of the skin Soon after the onset of his illness he had coughed up a small amount of blood He had gradually improved and a fortnight after the onset was allowed to get up His temperature was then normal and he felt quite well The next day he had a recurrence of his symptoms with shivering attacks and a high temperature which had continued until his admission to hospital He had never felt very ill and stated his appetite was gradually coming back His stools had been a normal colour during his illness In normal health he had to take "physic" to get his bowels open regularly

Twelve months previously the patient had had a similar attack of shivering and pain in the epigastrium but without jaundice He worked his own bakery which was situated in an old fashioned house and was formerly infested with rats

Examination and investigations—He was a jaundiced and emaciated man with no petechiæ or purpuric spots His mentality was normal Normal vesicular breathing was heard in the chest with a few crepitations at the bases The pulse rate was 110 and the heart sounds normal The abdomen was slightly distended. The liver was enlarged three fingers breadth below the costal margin and was very tender the spleen was not palpable but there was some tenderness on deep palpation in that area

A blood count on March 2nd showed hæmoglobin, 65 per cent red cells, 3 520,000 per c mm, white cells 20,000 (polymorphs 89 per cent, lymphocytes 11 per cent), colour index 0 92, mean diameter of red cells, 7 8 μ On the same day the fæces were found to contain a small quantity of bile pigment, and the urine scanty granular and hyaline casts abundant pus cells, a fair amount of albumin, and large amounts of bile salts bile pigments, and urobilin The reaction of the urine was acid and sugar and acetone were absent on injection into guinea pigs it proved non pathogenic On March 7th blood culture was negative after 96 hours and on the 10th cultures of fæces yielded no pathogenic organisms though films showed pus cells and few red cells The Wassermann reaction was negative Serum sent to the Wellcome Bureau of Scientific Research did not agglutinate formolised culture of *Leptospira hæmolyticus* and the adhesion test was negative (March 10th) Agglutination tests on blood (March 12th) were negative for *B typhosus B paratyphosus* A B and C *Brucella abortus* Bang *B dysenteriæ* Sonne Shiga and Flexner V W X Y Z *B enteritidis* Gaertner s bacillus and the salmonella group

Progress —The patient took fluids and light diet well. He was rather sleepless and tended to become delirious and restless at night He continued to have one rigor every 24 hours. The jaundice varied in intensity and at times almost disappeared. On the seventh day in hospital (twenty fourth day of illness) he began to have tenesmus and finally he passed several very watery stools *intimately mixed with blood and mucus* The *diarrhœa* was controlled with four doses of tinct opii (♏ 15) and mist cretæ (℥i) which also gave the patient a much needed sleep Collosol calcium 1 c cm for three doses was also given To control the rigors, quinine sulphate grs 10 t d.s was administered This had the desired effect

On March 10th in spite of taking fluids well the patient was becoming dehydrated and was rapidly drifting into a state of cholæmia Continuous intravenous glucose for 31 hours (approximately 10 pints of 5 per cent glucose in normal saline) had a slight beneficial effect but he was now sinking In view of the negative serological findings his condition was diagnosed as pylephlebitis of uncertain origin He died on March 18th

Post mortem findings —A full autopsy was carried out by Dr S C Dyke The body was that of a deeply jaundiced and emaciated man The abdominal cavity was the only area to show features of pathological interest *Four diverticula were present in the distal end of the* descending colon One of these situated in the posterior aspect of the colon, had perforated and formed a localised abscess on the inner and posterior side of the bowel. Pus had tracked up behind the descending colon and infiltrated between the layers of the transverse colon Pus was lying within the peritoneal cavity between the liver and stomach A tributary of the inferior mesenteric vein had become thrombosed. The thrombosis had involved the inferior mesenteric and the splenic veins The thrombus had become infected and the distal end was frank pus The liver contained a large number of abscesses varying in size from a pea to a tangerine Cultures from the pus showed *B coli* The spleen was large and septic ; the kidneys were normal

On admission this patient had signs and symptoms suggestive of Weil s disease and until it had been shown that the urine was non pathogenic to guinea pigs and that the serum did not agglutinate the spirochæte this diagnosis appeared the most likely

Weil s disease is usually transmitted through infected rats The onset is sudden with shivering and muscular pains high temperature (103 –105 F) anorexia, constipation and vomiting Jaundice appears about the fourth or fifth day Hæmorrhages are quite common either from the lungs stomach or rectum The liver is enlarged and tender and the spleen is not usually palpable The blood picture shows a leucocytosis (20 000–30 000 with 80–90 per cent polymorphonuclears) The initial fever falls in about 10–14 days and frequently a secondary fever with temperatures up to 103 F follows for about ten days The disease terminates in severe cases with convulsions and cholæmia.

This general description of the usual features of Weil s disease is at the same time an excellent summary of the illness of our patient and it was only the absence of any of the specific laboratory findings of Weil s disease that made the diagnosis untenable A diagnosis of pylephlebitis then became the only acceptable alternative though no suggestion could be made as to its origin The post-mortem findings of an acute diverticulitis were therefore a complete surprise

Although Mayo[1] has shown that the post mortem incidence of *diverticulitis in all people over forty* is 5 per cent. and in 40 000 X ray examinations was 5 7 per cent it is very rarely encountered at so early an age as thirty four This is borne out by Edwards[2] who examined 114 patients under thirty five with symptoms referable to the large intestine and did not once find diverticulosis Furthermore the case was unusual in that there were no previous symptoms pointing to diverticulitis and also in its mode of termination Though the formation of a localised abscess is one of the ordinary complications, an extension of the inflammation giving rise to pylephlebitis and such large liver abscesses is extremely uncommon

In conclusion I wish to thank Dr J H. Sheldon for permission to publish this case and for his helpful criticisms and advice and also Dr S C Dyke for the post-mortem and pathological reports

A CASE OF DIPHTHERITIC HEMIPLEGIA

By J M Todesco M.D Florence M R C S Eng D P H

RESIDENT MEDICAL SUPERINTENDENT TO THE BOROUGH HOSPITAL, CROYDON

HEMIPLEGIA is an uncommon complication of diphtheria.

A girl aged 9 was admitted to the Borough Hospital on March 18th 1936 as a severe case of diphtheria on the second day She had previously been well apart from measles and whooping-cough in 1929 and chicken pox in 1930

On examination there was extensive membrane over both tonsils profuse rhinorrhœa and enlarged submaxillary glands. She was cyanosed the heart sounds were very soft and rapid (120) She was given 44 000 units of antitoxin 24 000 being intravenous and another 16 000 units later in the day

By March 24th the throat was clean but the glands were still enlarged. Her colour was poor at times and the heart-sounds were still soft and rapid (120) April 1st : gallop rhythm was noted and the first sound at the apex was muffled.

On April 2nd she suddenly developed a right sided *flaccid hemiplegia, the face arm and leg being paralysed* The knee-jerks and the right abdominal reflex were absent and Babinski s sign was positive on the right She was drowsy speech was indistinct and she had incontinence of urine The pupils were equal large and reacting to light The first sound at the apex was still muffled but the rate slower (96) By April 3rd, though the right arm and right side of face were still completely paralysed there was very slight movement of the right leg Her speech was indistinct but she appeared to understand when spoken to Right palatal paralysis with difficulty in swallowing was now noted. April 7th : the paralysis of the right leg had disappeared and she could move it freely but the knee jerks were still absent Her condition was otherwise unchanged. A week later she could slightly flex and extend the right forearm but she could not abduct it or lift it voluntarily The right facial palsy persisted. Her speech was slurred and she took some time to answer questions She still had palatal paralysis a nasal voice and dysphagia The heart sounds were sharp and rapid (100) *Bilateral ptosis with slight right* internal strabismus appeared on April 25th

---

[1] Mayo W J Quoted by H C Edwards (19[illegible]) *Lancet* 1 1527

[2] Edwards H C (1934) *Lancet* 1 221

There was little change in her condition until May 6th, when there was more movement in the right forearm and hand She had definite right wrist drop with contraction of fingers and loss of hand grip She was now able to abduct her right arm By May 13th palatal movement had returned and the ptosis and right facial paralysis were less marked. The heart sounds were stronger and regular On May 22nd slight flexion of the fingers was possible By May 28th there was considerable general improvement, though the patient appeared mentally confused at times She could now flex her right wrist slightly and use her fingers, though they were still contracted

She got up for the first time on June 6th, and a few days later could take a few steps with support Her right leg and thigh muscles were wasted, the knee jerks absent, and she dragged her right foot when walking The right hand and wrist showed marked improvement By June 30th she could use her right leg and foot and lift this off the ground, and grip objects with her right hand, though she still had difficulty in extending her fingers

When discharged from hospital on July 21st her gait was practically normal, though no knee jerks were obtained, but there was still some weakness in the right facial muscles, right wrist, and fingers The speech was normal

Points of interest in this case are the sudden onset of a flaccid hemiplegia in the third week of a severe case of diphtheria, with rapid recovery in the use of the right leg and comparatively early recovery of the paralysis of the face and right arm

In similar cases reported during the last few years by Benn and Alstead (1931), and Chamberlain and Alstead (1931), the hemiplegia though flaccid at first later became spastic, with a permanent lesion in the affected leg This does not appear to have occurred in this case The hemiplegia might possibly have been due to diphtheritic embolism or thrombosis, though there was no apparent permanent damage to the heart as has been noted in other cases

I am indebted to Dr Oscar Holden, medical officer of health for Croydon, for permission to publish this case

FLUORESCEINURIA

By George Discombe, B Sc Lond
JUNIOR DEMONSTRATOR OF CHEMICAL PATHOLOGY
ST BARTHOLOMEW'S HOSPITAL LONDON

The urine passed after a dose of fluorescein shows an intense green fluorescence If the dye has been deliberately administered such a urine will cause no surprise but if it has been given as a practical joke, or in a proprietary drug some alarm may be caused At St Bartholomew's Hospital two cases have lately been seen in which it followed the use of Ephazone, a proprietary remedy for asthma which is claimed to contain 28 different drugs

The dye is excreted fairly rapidly by the kidneys As an experiment, one tablet of ephazone was given to a man of 70 kg weight and fluorescein was found in the urine passed at the end of the first hour, it was still present at the end of the eighth hour, but absent at the end of twenty four hours The greater part of the dye was excreted during the first four hours In the serum of blood collected at the end of the first hour no dye could be detected

The presence of fluorescein in urine should be suspected if a normally coloured urine shows an intense grass green fluorescence If the dye is present, spectroscopic examination should show an absorption band between 506–482 mμ (maximum at 494 mμ) (almost identical with that of urobilin) with general absorption on the blue side of 430 mμ, though in concentrated solution the band cannot be distinguished from the general absorption On acidifying such a urine with hydrochloric acid the fluorescence and absorption band disappear

SEPARATION AND IDENTIFICATION

The dye may be separated from urinary pigments and, if present in fair concentration can be converted to eosin. The urine (50–500 c cm) is acidified with 1–2 c cm concentrated hydrochloric acid and extracted with 25 c cm. amyl alcohol The amylic layer is separated and extracted first with 100 c cm water containing 20 drops 40 per cent. caustic soda and then with 50 c cm water the washings are united in a 250 c cm measuring cylinder, 50 c cm. alcohol is added to prevent turbidity, and the quantity is made up to 250 c cm with water A clear solution is thus obtained which shows the characteristic fluorescence yellow colour, and absorption band of the dye at a dilution greater than one part of dye in 5,000,000 of urine

To convert to eosin, 100 c cm of the clear alkaline solution is made acid with hydrochloric acid and 1 c cm bromine water added After mixing the solution is made alkaline with caustic soda, when it becomes pink with a yellowish green fluorescence, and if fairly concentrated shows an absorption band between 515–525 mμ (b to E lines) This reaction is not easily obtained with dilute solutions of fluorescein, owing to some destruction by excess bromine and thicker layers of solution (2–4 in) should be examined for the bands With both dyes the fluorescence is visible at much greater dilution than is the absorption band. even when 4 in layers are examined with the spectroscope,

In examining urine for eosin it was noticed that the absorption bands of eosin varied with solvent In water and diluted alcohol only one band, between 434–560 mμ, with a maximum at 515–525 mμ, can be seen, in amyl alcohol either one or two bands may appear, according to concentration, the more intense being centred at 532 mμ the weaker and more diffuse at 496 mμ

To test for eosin in urine it was found convenient to acidify 200 c cm urine with 1 2 c cm hydrochloric acid and shake out with 25 c cm amyl alcohol, to the separated amylic layer an excess of solid sodium acetate is added and the solution examined spectroscopically Using a 1 in layer the band at 532 mμ is visible at a dilution of 1 in 750 000 corresponding to about 1 in 5,000,000 in the urine An hour after 0 1 g had been taken by mouth the dye was present in the urine, it could be detected up to the end of the sixth hour, but not subsequently

The figures for the wave lengths of absorption bands are not of great precision Where comparable, they agree well with those obtained by H S Uhler and R W Wood (Atlas of Absorption Spectra, Washington, 1907)

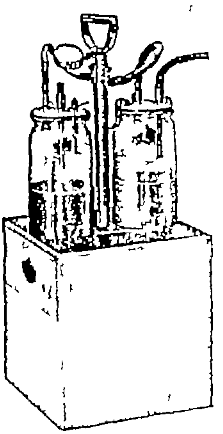
NEW INVENTIONS

AN ELECTRIC ASPIRATOR

The frequency of pleural effusions in artificial pneumothorax treatment and the necessity for their removal demands efficient and labour saving apparatus An aspirator has therefore been designed with the following main objects —

(1) To remove fluid by constant suction
(2) To eliminate all fatigue for the operator
(3) To allow the operator to have complete control over the position and direction of the aspirating needle throughout the operation and if necessary at the same time to be able to control a pneumothorax needle to introduce air into the thorax

The apparatus consists of an electric motor which drives a small but very efficient suction pump This is enclosed in a felt lined box and controlled by a foot switch, which when not in use can be stored in another compartment The suction pump is



connected to a graduated bottle in the lid of which are fitted two valves one automatically cuts off the suction when the bottle is full thereby preventing any fluid reaching the motor and the other regulates the amount of suction which can be varied from 2 to 600 mm of mercury The degree of suction is registered on a manometer conveniently placed in a prominent position A second graduated receiver is provided so that in cases where there is a profuse amount of fluid the operation can proceed without having to empty the bottle (see Figure) By reversing the tubes the apparatus will give positive pressure and since the motor is controlled by the foot it leaves both hands free to direct an insufflator or nebuliser quite accurately on any desired area in laryngeal work Owing to the excellent degree of suction obtainable the apparatus becomes useful in bronchoscopic work for it is smooth and continuous and can be graduated accurately Complete control over the aspirating needle is obtained and all jerky movements are eliminated As the operator's hands are free the patient and needle can be placed in any desired position so that a complete aspiration of the fluid present is possible

A lighter apparatus on the same principle is made for ward use. In this the motor and foot switch are not enclosed in a box so that although the instrument gains in portability it is not so silent and compact as the heavier model.

In designing the apparatus I have been assisted by Mr C Gore-Yeo who has made some valuable suggestions that have been adopted. The apparatus is made by John Bell and Croyden of 50 Wigmore street, London W 1

FREDERICK HEAF M.D Camb
Formerly Medical Superintendent of the Colindale Hospital Hendon N W

MEDICAL SOCIETIES

ROYAL MEDICO-CHIRURGICAL SOCIETY

AT a meeting of this society at Glasgow on Dec 18th Mr G H EDINGTON the president, in the chair a short paper on

X Ray Dosage

with reference to malignancy was read by Dr FERGUS L HENDERSON who discussed the difficulty of accurately measuring X ray doses. He said that, while it was now possible to determine accurately the number of *r* units that were being given it was impossible to forecast exactly what effect any particular dose would have on the skin of any patient. The common procedure to-day was to give heavy doses of X rays well filtered over a period of 3–6 weeks The tendency therefore of patients to omit a day's treatment for various reasons made it impossible to give accurate doses He urged that wherever possible patients should be told the truth about the disease from which they were suffering since it was otherwise almost impossible to get them to submit to the suffering and discomfort from the heavy doses of X rays required to produce retrogression of a tumour growth

Dr NOAH MORRIS in a paper on the significance of

Plasma Phosphatase in Bone Disease and Jaundice

said that since Robison's work on phosphatase had been applied to clinical conditions variations in plasma phosphatase had been studied in numerous pathological states especially those affecting osseous tissue The presence of the ferment in the blood might be taken as a rough estimate of its production in the tissues but it was quite possible that an increase might be due to diminished utilisation in its place of origin Plasma phosphatase was much increased in Paget's disease generalised osteitis fibrocystica moderately raised in rickets, osteomalacia and bone cancer and slightly above normal in osteoporosis and osteopetrosis In multiple cystic tumours of bone a great increase in plasma phosphatase might be very useful in determining whether or not there was over production of the parathyroid hormone and therefore whether operation was needed It was not of much value in the early detection of either Paget's disease or osteitis fibrocystica since changes were generally seen in the skiagram before the phosphatase was increased An analysis of phosphatase estimations in a group of 500 infants and young children had shown that while in a small number of cases the phosphatase was not increased even in the presence of clinical and radiographic signs of rickets there was on the whole a moderate degree of correlation between the amount of the plasma phosphatase and the severity of the disease In untreated active rickets the phosphatase continued to increase and a stationary value might be taken as early evidence of healing The rate of fall depended on the dosage of vitamin D The estimation of plasma phosphatase had a place in the diagnosis of the preclinical stage of rickets but it could not by itself be used to indicate in a single patient either the severity of the rachitic process or the presence or absence of healing

While it was true that the phosphatase was generally much increased in cases of obstructive jaundice but moderately raised in toxi infective and within normal limits in hæmolytic jaundice there was such an overlap of figures that the determination of plasma phosphatase was of little value in making a decision about the nature of the jaundice Clinical data obtained in association with Mr A B Kerr showed that removal of bile by means of a bile fistula might lead to a great increase in the plasma phosphatase without causing a significant alteration in the bilirubin content of the blood It was known that the absence of bile from the duodenum led to a defective absorption of lime Personal experience had indicated that a calcium poor diet caused a pronounced increase of plasma phosphatase It was suggested therefore that in jaundice and other conditions an increase in plasma phosphatase occurred whenever the retention of lime was insufficient to meet the demands of the osseous tissue

Dr ANGUS SCOTT described in detail a case of chronic adhesive pericarditis of tuberculous origin which operation had failed to relieve

REVIEWS AND NOTICES OF BOOKS

Clinical Psychology

A Handbook of Children's Behaviour Problems
By C M Louttit, Director, Indiana University Psychological Clinic New York and London Harper and Brothers 1936 Pp 695 12*s* 6*d*

The child guidance movement is gradually developing a literature of its own Recently there was Dr Kanner's book, frequently quoted in the book under review, and written from the standpoint of a psychiatrist Mr Louttit is a psychologist but, while psychological aspects naturally predominate in his book, he is fully cognisant of the contributions that medicine education, and sociology have to make to the working of a psychological clinic, and gives due attention to those aspects The book is comprehensive in its survey, covering not merely the personality and behaviour problems strictly so called, but also the grosser abnormalities such as mental defect and the psychoses as they affect children There are sections on speech and sensory defects, on neurological and physical disabilities such as encephalitis, epilepsy, and even malnutrition A preliminary chapter deals with diagnostic methods, briefly but sufficiently to put the student on the true line of search for fuller information

In a book covering so wide a range we can do no more than select one section for special mention The chapter on mental defect is practical and sound in its teaching The author sees no hope in gland-therapy or in psycho analysis for improvement of intelligence, but contends that the defective need not be a social problem if he is adequately trained. His classification of the grounds for institutional custody or training is a useful one for examiners The preventive aspects of mental hygiene are not overlooked Growth and guidance in psychosynergic traits (temperamental and emotional) are, he contends, as important as growth and guidance of intelligence A feeling of security is fundamental to a child's mental growth, and this calls for stability in the home, and stability in his teachers in school

As a text book for students of clinical psychology this work is admirably adapted for its purpose The treatment in each section is full, the arrangement systematic, the case histories illustrative and helpful. It is written in an easy style and may be commended not only to workers in the child guidance movement but to the pædiatrician, and especially to the practitioner who wishes to supplement his knowledge of the physical development of the child by some understanding of the concurrent psychological growth

The Queen Charlotte's Textbook of Obstetrics

Fourth edition By the Eight Members of the Clinical Staff of the Hospital London J and A Churchill Ltd 1936 Pp 674 18*s*

Regularly, and precisely at intervals of three years, the staff of Queen Charlotte's Hospital, albeit with assistance from outside, produce (or should we say reproduce) a new edition of their text book The first child, though long overdue was well received, and each successor has been accorded an even more enthusiastic reception This edition differs from its predecessors in many respects The sections dealing with the toxæmias and vomiting in pregnancy have been rewritten. The authors will not admit that the underlying cause of hyperemesis gravidarum may be a neurosis, they regard the neurotic element "as a very important factor in many cases, yet believe that in many, if not all, there is some additional factor of more or less importance" The chapter dealing with the toxæmias is essentially practical, concise, and businesslike Much rubbish has been cleared away, the student and practitioner are not presented with several alternative methods of treatment One line of treatment, pre eminently sound and full of common sense, is described, and this is based for the most part on the hospital practice

The difficult subject of puerperal sepsis receives close attention We know of no other text-book of obstetrics in which it is treated so thoroughly, full use being made of temperature charts and the coöperation of the staff of the research laboratories In the chapter on anæsthesia in obstetrics are described various methods of inducing narcosis or anæsthesia It would appear that the chloral bromide laudanum mixture, the use of scopolamine narcosis for the first stage, and the administration of small quantities of chloroform vapour by the Junker's inhaler during the pains of the second stage still hold the field The dangers accompanying the use of the barbiturates and the practical difficulties of nitrous oxide anæsthesia are clearly and fairly set forth

The book is a faithful exposition of English obstetric practice Paper, printing, and illustrations are of the best It may be confidently recommended to all who learn or practise obstetrics

An Introduction to Dermatology

By E H Molesworth, M.D, Ch.M. Sydney, Lecturer in Diseases of the Skin, University of Sydney, Dermatologist to Royal Prince Alfred Hospital and Prince Henry Hospital, Sydney, &c. London J and A Churchill Ltd. 1937 Pp 520 25*s*

A foreword by the late Prof Joseph Jadassohn, who did so much for dermatological science, and who will rank with Darier, Sabouraud, and Bloch as a leading representative of the era in which he worked, characterises Dr Molesworth's book as "the fruit of most serious labour" and this is the impression which it will generally establish

The arrangement follows classical lines, and is well balanced in a sequence of thirteen chapters There is a pleasing brevity of anatomical and physiological description, and the author passes almost at once to the consideration of the effects of deficiency and excess of sebaceous secretion, a matter of fundamental importance not only in the diagnosis but in the course and treatment of all cutaneous disease. Seborrhœa and ichthyosis are both regarded as in some measure hereditary in tendency, and grouped with hypertrichosis and hyperidrosis, tylosis and epidermolysis bullosa in one chapter as abnormalities Much thought and study have been given to the chapter on the allergic diseases The extensive literature of this subject, and the confusion that has arisen by reason of a careless diversity of terms and nomenclature, render a clear conception of the present state of our knowledge a task of the utmost difficulty The author has done wisely in avoiding an involved discussion of the theoretical problems in favour of certain practical applications such as skin testing desensitisation and the uses of tuberculin and trychophytin in diagnosis and treatment. That all our present methods of desensitisation are "capricious" in action is a truism which none will dispute. The author has a good deal to say on the subject of leprosy to which Australian and Polynesian aboriginals are *highly susceptible. He protests against* compulsory segregation as tending to concealment of symptoms in the early stages to the development of "leprophobia" and as being unfair in view of much less stringent regulations in the case of far more infectious diseases—syphilis and tuberculosis

But it is in his chapter on radiotherapy that Dr Molesworth really excels Much of it is highly technical and beyond the comprehension or the requirements of the average reader It seems that he prefers the X ray tube to all other methods of radiation treatment for cutaneous epitheliomata (so common in Australia) and finds but little use for radium and scarcely any for the surface applicator In this respect, as he doubtless knows, the balance of dermatological opinion is against him and in delicate and inaccessible situations such as the angles of the orbit radium plaques will continue to be employed Worthy of careful study is his claim for the treatment of cavernous nævi in young children by X radiation and the account of an original technique for the purpose.

In this book Dr Molesworth has added to a literary achievement which is already considerable It should have a great success in Australia where we believe it to be the first production of its kind.

Prelude to Chemistry

By JOHN READ ScD F R S Professor of Chemistry in the University of St Andrews London: G Bell and Sons Ltd 1936 Pp 328 12s 6d

THE search for the philosopher's stone and the elixir of life occupied some of the busiest wits of the world for more than 1000 years and some reflection of the ideas and notions which guided the hunt are *still perhaps to be found in the less sophisticated* arts of medicine Alchemists at any rate cleared the field for what we know as chemistry and Prof Read gives an interesting account of their doctrines and how they thought and what they did. It all seems very strange and fantastic to us but before we despise or laugh at it too much it is well to remember that Isaac Newton was a keen member of the cult and that our successors 200 years hence may find our own principles and practice equally remote from reasonableness The abundant and excellent illustrations are due to the Carnegie Trust

Essentials of Modern Medical Treatment

By VINCENT NORMAN M D M R C P Lond F R C S Edin D P H Lond London: Hutchinson's Scientific and Technical Publications 1936 Pp 200 10s 6d

BOOKS on treatment continue to appear in astonishing numbers Dr Norman writes as a practitioner for practitioners aiming above all things at brevity He takes the main diseases of the text books and tells the doctor what treatment he should apply or what he may try for each one In general he is orthodox Much of his advice is obviously the product of experience and judgment and consequently good Some is clearly second hand Drugs and prescriptions figure largely and he has a surprising faith in some e g administration of parathyroid extract by mouth and anterior pituitary for hypotension Although in such respects he is a little less than modern he mentions most of the outstanding therapeutic discoveries of recent years Some of his "don'ts" are very welcome such as "there is no need to restrict the consumption of meat in migraine" His book may be very useful to the practitioner who has little time and not a great deal of experience

Public Health and Hygiene

A Students Manual. Second edition. By CHARLES FREDERICK BOLDUAN M D Director Bureau of Health Education Department of Health City of New York and NILS WILLIAM BOLDUAN M D Children's Medical Service Bellevue Hospital New York. Philadelphia and London: W B Saunders Co Ltd 1936 Pp 371 12s 6d

THE senior author of this book is one of the leading American hygienists and in this manual he has attempted and achieved the ambitious task of presenting the theory and practice of modern hygiene in a simple, short narrative as free as possible from technical expressions and within the understanding of any intelligent person Though this is a second edition it has been so completely revised that it is practically a new work. As a students manual it is too slight for British public health students but is eminently suitable as an introduction to epidemiology for those taking the curriculum of general medical education It is equally serviceable for nurses taking the health visitor's certificate and is within the capacity of social workers interested in public health. Unfortunately from our point of view it is American based mainly on New York practice and experience but this does *not detract from its value to British* students, except in so far as laws and regulations are concerned The characteristic of the book is the approach to preventive medicine through history However important history may be in general medicine it is vital to epidemiology which largely is history For this reason the manual fills a gap which is ill bridged by English medical literature It is short, concise, well illustrated and preeminently readable. The portraits and reproductions of old prints are valuable

Neuro embryology

An Experimental Study By SAMUEL DETWILER Professor of Anatomy College of Physicians and Surgeons Columbia University London: Macmillan and Co Ltd 1936 Pp 218 16s

THIS is the second volume in a series of monographs on experimental biology Books of this sort are needed for there are many to whom the findings of experimental biologists are of interest or of great importance who have not the opportunity or time for searching the extensive and scattered literature This book is an excellent example of the kind of thing required *It is clearly written and well put together* so that the reader need be in no doubt about the bearing of the experimental work on the question under consideration Prof Detwiler deals with such matters as the rôle of the neuroblast and sheath cell in development the behaviour of nerves in the presence of grafted limbs the responses of nerve centres to peripheral alterations the proliferation of neural cells under various conditions He describes many interesting experiments on somites and on segmental characters in the cord, and devotes a chapter to observations on the giant Mauthner's cell and the ear vesicles of certain fishes and amphibians Results, of course, cannot be applied at once to human material, but many of them may be found to have a wider bearing, for example, the heterotopic grafts (lateral to somites) of regions of the cord, leading to great hyperplasia, hold a possible interest for the pathologist The author does not lay much emphasis on the magic word "gradient"—for which many will be thankful, he regards the views of Weiss on direction of nerve growth as a more reliable guide Altogether an excellent monograph

Statistical Methods in Biology, Medicine and Psychology

Fourth edition By C B DAVENPORT, Carnegie Institution of Washington, and MERLE P EKAS, Northeast High School, Philadelphia New York John Wiley and Sons London Chapman and Hall Ltd 1936 Pp 216 *13s 6d*

THIS little handbook first appeared in 1899 Since then the use of statistical methods has become much more widely extended in every branch of science, and the number of English text books has been steadily increasing both in this country and the United States This particular one, in spite of complete revision, can hardly be regarded as a serious competitor with the best of them, but it may well be useful to those who like to be told what to calculate without much elaboration of the when and why To those interested in the latter it seems odd, for instance, to find the probable error introduced before the standard error, and the latter defined as 1/0 6745 times the former And to include correlation due to a common factor affecting both variables under the heading "spurious" seems to give a connotation to that term that might lead a student to confuse correlation with causation

The arithmetical examples are clearly set out, and the last fifty pages are devoted to useful formulæ and tables, e g a short table of values of the normal probability integral a table for use in the analysis of variance tables of powers and factorials of integers, &c The inclusion of these certainly makes it a convenient book to possess, even by those who prefer to rely on more elaborate text-books for their guidance in statistical methods

Modern Urology

Third edition By HUGH CABOT, M.D, LL D, C M G, F A C S, Professor of Surgery, Mayo Foundation, Graduate School of University of Minnesota London Henry Kimpton 1936 2 vols Pp 951 and 862 *£4 10s*

TWENTY years have elapsed since the first edition of this important work appeared, and twelve since the second When the first preface was written by the same editor urology was in its infancy It was termed genito urinary surgery and usually combined with the practice of syphilology, few people regarding it as a specialty even in that land of specialism America Now urology has grown to manhood and is recognised by all (except certain diehards) as a special branch of medicine with its own exponents its own armamentarium, and its own literature In the last named the book before us occupies an important place Not only has America contributed many of the most valuable advances in this science, but Dr Cabot has an experience that is second to none He has not attempted to cover the vast ground by his unaided efforts, he has instead chosen a team over whom he has exercised the function of a wise and experienced captain. Death has removed several of the writers who contributed to the earlier editions, but the general standing of the present contributors is high

In the first volume, J C C Corbus provides an excellent description of those rarer entities amongst venereal diseases chancroid, granuloma and lymphogranuloma inguinale So much confusion exists on the subject of what are loosely known as soft sores and chancroids, that an accurate and complete description of non syphilitic infections of the genitals is to be welcomed Later in this volume appears the completest extant description of that controversial subject, the pathogenesis of genital tuberculosis. The final third is devoted to an account of prostatic obstruction by H H Young, Lloyd G Lewis, Bentley Squire, and H C Bumpus Although many changes have occurred in America in the technique of transurethral prostatectomy during the last few years, it seems that the modification of the suprapubic operation that has aroused much interest in England namely the Harris operation, is not regarded with much favour

The second volume is devoted to diseases of the bladder, ureters, and kidneys Unfortunately the chapters on urinary infections were written too soon to allow of the inclusion of the latest method of treatment by sodium mandelate A graver omission is the lack of reference to dyectasia vesicæ or obstruction of the bladder neck apart from prostatic enlargement These cases of what the French formerly termed "prostatisme sans prostate" are now accepted as a clinical entity, and might well have had a special heading

As a work of reference this book should be valuable, and the complete and up to-date bibliography at the end of each chapter adds greatly to its value.

REPORTS AND ANALYSES

VERMOUTH STAMBOIS, RED AND DRY

STAMBOIS (FRENCH VERMOUTH) LTD 5 MILES STREET,
LONDON S W 8

ON analysis these vermouths were found to have the following composition —

	Red	Dry
Present gravity	1027 9°	1001·01°
Alcohol by volume per cent	15 5	18·0
Equivalent to proof spirit per cent	27 1	31·4
Fixed acidity (as tartaric acid) per cent	0 51	0·56
Volatile acidity (as acetic acid) per cent	0 05	0 03
Total extractives per cent	12 0	5 85
consisting of—		
Cane sugar per cent	Nil	Nil
Grape sugar (dextrose) per cent	9 41	3 61
Ash per cent	0 34	0 33
Other extractives per cent	2 25	1 91

These two wines possess the agreeable palate and aroma characteristic of the best sweet and dry vermouths The sugar content is lower than in some brands The wines are fortified From a consideration of the analyses there is no evidence that sugar other than that natural to the constituents has been added No salicylates or other deleterious substances were found Skilful blending has resulted in products free from excessive sweetness or dryness

THE LANCET

LONDON SATURDAY JANUARY 9 1937

THE RISK OF ATTENDANCE ON THE TUBERCULOUS

OPINIONS have long differed and differ still about the risks of infection run by nurses and others in contact with consumptive patients More than a century ago, when KEATS went to Italy towards the end of his last illness fear of contagion there was so great that he had to haul up his food through his window At that time in England phthisis was considered no more than a hereditary taint and this belief was only gradually shaken after KOCH's discovery of the tubercle bacillus In an address to the British Medical Association at Worcester in 1882 THEODORE WILLIAMS[1] considered the evidence of contagion among doctors nurses and domestic staff working at the Brompton Hospital since its opening in 1846 Although allowances must be made for failure to diagnose lesions which would now be visible on X ray examination, his observations have an important bearing on the problem as we have it to-day on account of the fact that the degree of exposure to infection was then far higher than would now be tolerated in any hospital. For instance as he tells us, spittoons were not disinfected unless the odour became unpleasant the system of ventilation, moreover was designed primarily to produce a warm draught-free atmosphere In winter the air was heated before admission, and before 1877 when extraction was helped by the insertion of steam pipes in the ventilating towers the removal of foul air had been so defective in parts of the building that outbreaks of erysipelas and sore throat had occurred in 1869 and 1875 In spite of these fearsome conditions of 75 house physicians who had been in residence since 1867 (WILLIAMS had traced all except 3) 69 were well and working 2 had died from consumption (but one of these had had hæmoptysis before becoming a resident) 1 had died from another cause and 1 had become consumptive but had recovered Between 1846 and 1867 1 nurse contracted phthisis while in the hospital 3 more died from this disease after leaving 2 of them many years later Between 1867 and 1882 out of 101 nurses 1 died of phthisis and 2 from other causes The follow up of the domestic staff —maids and porters—was too imperfect for statistical purposes 1 death from phthisis is recorded and 6 from other causes In view of the fact that at this time the death rate from tuberculosis was about four times its present figure the observations of WILLIAMS do not suggest that exposure to massive doses of tubercle bacilli was then highly dangerous to adults

Until recently the general attitude in this country has been that provided proper precautions are taken the risk of a nurse catching tuberculosis from a patient is slight But this equanimity has been shaken by a number of reports, coming chiefly from Scandinavia and the United States Two important papers[2] set out clearly the results of recent investigations In one of these Dr J HEIMBECK of Oslo records his observations over more than ten years, on a nursing personnel of about twelve hundred all of whom were exposed to infection He notes the different effect of such exposure on nurses who had escaped childhood infection from those who were already Pirquet positive when they began their hospital work. Among 625 nurses Pirquet-positive on arrival there was no death from tuberculosis but 27 showed signs of tuberculous activity (4 with T.B + sputum) Of 280 nurses Pirquet negative on arrival there were 10 deaths from tuberculosis and 96 showed signs of activity (13 T.B + sputum 2 meningitis) So striking was this contrast that since 1927 many of the Pirquet-negative nurses have been given B C G In a final survey HEIMBECK gives the following figures —

(1) Morbidity amongst those who have passed the primary infection without becoming ill 800 persons—3502 observation years—30 persons ill Morbidity: 8 5 per 1000 observation years.

(2) Morbidity amongst those Pirquet negative (107 of whom still negative after B C G): 387 persons—675 observation years—118 persons ill. Morbidity 152 9 per 1000 observation years.

(3) Total morbidity among B C G vaccinated: 489 persons—1200 observation years—33 persons ill. Morbidity 26 1 per 1000 observation years

(4) Morbidity amongst those vaccinated until Pirquet positive: 287 persons—910 observation years—8 persons ill (1 death) Morbidity: 8 3 per 1000 observation years.

The other paper by Dr E S MARIETTE of Glen Lake Sanatorium Minnesota contains an impressive review of the subject Since 1921 of 2084 nurses X rayed at the sanatorium 1567 have been followed up of this number 7 7 per cent had evidence of adult tuberculosis on the first film and 4 1 per cent later developed phthisis Although none of this group died MARIETTE concludes that there is a certain hazard in nursing and that nurses have the right to expect adequate precautions and control. Since 1932 305 student nurses have been tuberculin tested of 191 (52 per cent) tuberculin positive 152 were followed up and 1 developed adult tuberculosis of 174 (48 per cent) tuberculin negative 141 were followed up and 4 developed adult tuberculosis These figures support, on a smaller scale HEIMBECK's conclusion that it is the tuberculin negative nurse who runs the greater risk MUCKE[3] whose investigations cover 4281 nurses and nuns at the Eppendorf Hospital found 150 cases of tuberculosis before 1918 the incidence was only about 1 per cent but it subsequently increased to 4·0 per cent. Persons with a negative tuberculin reaction it has been suggested have two chance when exposed to tuberculosis the argument being that they may develop a benign first infection Logically the argument would lead to the personnel of a sanatorium being treated like a herd of T T cattle and the positive reactors eliminated But the facts at our disposal do not support this line of reasoning, although admittedly there is some discrepancy between the observations on nurses and similar surveys of other groups such as native miners in South Africa and students in the United States It is significant that Dr MARIETTE did not at first tuberculin test his nurses because he thought they would all be positive, yet when routine tests were made in 1932 the proportion of negative reactors was 48 per cent

---

[1] Brit med J 1882 2 618

[2] Tubercle December 1936 pp 97, 103

[3] Beitr Klin Tuberk [illegible] 155

In this country the Joint Tuberculosis Council has just published a memorandum based on material collected from 38 hospitals and sanatoria The usual age at which probation nurses are accepted is, it seems, 18 years, and in view of the special susceptibility to tubercle of adolescent females the Council deprecates the practice in certain areas, where there is a shortage of candidates, of reducing the age of entry to 17 Hours of work varied from 48 to 77 per week, the average for probationers being about 60, a somewhat longer period than that recommended by the College of Nursing At present only about half the institutions circularised make a routine X ray examination of their nursing staff, the Council recommends that the staff should be thus examined at least once a year wherever nurses are exposed to tuberculous infection No mention is made in the Council's memorandum of tuberculin tests, but Dr PETER EDWARDS [4] has just published a small series from the Cheshire Joint Sanatorium which appears to support HEIMBECK'S findings On joining the hospital staff 54 nurses were Mantoux-positive and 11 negative, of the latter group 2 developed tuberculosis, both within three months An investigation on a larger scale is being carried out under the Prophit Trust The practical issues raised by these observations are momentous It appears that whereas a few decades ago tuberculous infection was almost universal, by the time adult years were reached, this is no longer the case The great diminution in the number of open cases of tuberculosis, the gradual education of the public in matters of hygiene, in particular as regards spitting in public, and the provision of clean or pasteurised milk have conspired to make tuberculous infection less frequent in youth No doubt the reduced risks of infection achieved in these ways have contributed to the fall in the mortality rate, but at the same time the dangers of infection in early adult life seem to have become more serious than they were in THEODORE WILLIAMS'S time Doctors and nurses who come into close contact with open cases of tuberculosis will either have to be chosen from amongst the positive reactors or to undergo some form of inoculation to make them tuberculin sensitive As the proportion of negative reactors rises the dangers of one spouse infecting the other must also be expected to increase

FRACTURE CLINICS

THE great majority of all fracture cases are treated at hospitals, and the responsibility for the efficient treatment of fractures has in recent years come to lie very heavily on the conscience of hospital staffs After conference between representatives of the British Medical Association and the British Hospitals Association a questionnaire was sent out to discover how far the hospitals had accepted the principle of segregation of fracture cases in special departments under the charge of a qualified team of surgeons The answers received from fifty-one hospitals are tabulated in a memorandum (No 104) recently published by the Central Bureau of Hospital Information These show that the principle has been accepted and is already being acted on in forty-one hospitals, three others have the scheme under consideration, seven have considered and rejected it The size of the hospital and the numbers of fractures attending for treatment influence the replies A small hospital, even though accepting the principle of placing the whole fracture service under control of a specialist in bones and joints, obviously is not in a position to appoint " a team of whole time assistants "—to quote the wording of the questionnaire The Royal United Hospital at Bath, for instance, with 190 beds, agrees to the appointment of a specially qualified head of the fracture service, but answers " numbers insufficient " to the suggestion of appointing a team of whole-time assistants Others answer " Yes, but not necessarily whole time," or words to that effect From the account of the Cardiff municipal accident service, which we print on page 107 of this issue, it will be seen that with an average of 100 cases under treatment it has been found possible to retain a resident assistant surgeon, chosen specially for his knowledge of fractures, by combining the work of the fracture clinic with certain hospital work outside it

The hospitals were asked to give an opinion as to the usefulness of a whole time salaried officer of the almoner type whose duties would be to keep the records of cases The practice varies considerably In some cases the records are kept by the registrar, in others by the massage sister, frequently a part-time clerk is employed It is obviously a waste of the surgical assistant's time for him to write notes, answer in his own hand letters from general practitioners, and be responsible for the filing of records, when all this can be done at his dictation, and more efficiently done, by a clerk The fact that much tedious clerical work has been imposed on the medical staff no doubt explains why records are not available at so many hospitals Several hospitals stated that the reluctance on the part of the general surgeons to give up their fracture work was an obstacle in the way of placing all fractures under the control of one experienced specialist Out-patients may be referred to a particular surgeon who wishes to deal with them himself Nevertheless a large number of the hospitals consulted were of opinion that all ambulant fractures should attend the special department throughout their treatment—this not so much to take fracture treatment out of the hands of a general surgical staff who are often quite competent to deal with it, but to remove the responsibility from the young casualty officer who rarely is The new hospital at Southend-on Sea provides that any fracture case specifically sent to one of the general surgeons may be treated by him but he is invited to refer it to the fracture clinic

NASAL SINUSITIS IN CHILDHOOD

Do children often have infected nasal sinuses ? Opinions differ In the United States when a child has an upper respiratory infection the diagnosis is almost as likely to be sinus suppuration as tonsils and adenoids On the other hand HAJEK of Vienna in his classical work Nasal Accessory Sinusitis' written in 1026 reported that he had seen only 4 cases of antral empyema proved by puncture in children between the ages of five and twelve and said that the fantastic reports of some American authors are to be regarded with great scepticism as their methods of examination give us no assurance of the reliability of their results ' In this country the general opinion seems to be that the disease is not very common although within the last ten years it has been realised that it is commoner than was previously supposed there is also an impression that in children sinusitis is usually transitory with a tendency to recovery

Mr JAMES CROOKS [1] has now published the results of an important investigation which he has made at the Hospital for Sick Children Great Ormond street from which it appears that the disease is far more frequent than is usually believed and less likely to clear up spontaneously His material falls into two groups In the first both antra were aspirated in 100 children while undergoing tonsillectomy This routine was chosen for four reasons the patients were suffering from an upper respiratory complaint, possibly due to antral infection the puncture could readily be done while they were under the anæsthetic it was desired to prove if it was true or not that removal of tonsils and adenoids usually cleared up an antral infection and finally children with a temporary infection from a cold would be automatically excluded Any antrum containing pathological matter was to be subjected to aspiration again six months later Of these 100 children 24 were found to have pus or mucus in an antrum (6 of them in both antra) and in only 9 of these were the antra clear at the end of six months in other words 15 per cent had chronically infected antra Their average age was seven years The fluid sucked from the antra was examined bacteriologically by Dr A C SIONX in all the 100 cases and it is remarkable that of those antra that contained neither pus nor mucus only about half were sterile Mr CROOKS does not explain this anomaly but says that it seems reasonable to suppose that the great majority of healthy antra are sterile though it is not accurately known how often a healthy sinus contains a few organisms Some of the antra that still contained muco-pus after six months were sterile as were 3 containing muco pus at the first puncture, it has been observed that organisms may die out in a long standing abscess such as a pleural empyema, and this may presumably also happen in a nasal sinus The pneumococcus was the organism most often found in these children. The second group is composed of children who presented clinical evidence of antral disease Detailed investigation was stopped when their number reached 76 making with the first group a total of 100 cases but many more cases have since been explored and in the last two years mucus or pus has been washed out of the antra of over 500 children at the hospital The sexes were equally divided, and the average age of the 76 was seven and a half the youngest being two and a half and the oldest twelve 42 were under seven Of the total 37 could be classified as cured in 35 by antral lavage at an average of between two and three washings and in 2 by intranasal antrostomy , of the remainder 26 were improved but 13 were no better though 4 of them had antrostomy

Any or all of the accessory sinuses may become diseased but the antra were chosen as the subject of this investigation because they are much the most often affected and because examination of the other sinuses is far harder in children Many interesting details about the diagnosis symptoms and results are given Mr CROOKS thinks that apart from proof puncture radiography is the most accurate means of diagnosis Nasal obstruction is frequently severe and he believes that the adenoid facies is more often the result of sinusitis than of adenoids As a cause of otitis media sinusitis is second only to adenoid infection and should always be suspected if removal of the adenoids is ineffective A child suffering from sinusitis is usually in poor health losing interest in work and play and becoming morose, ill tempered and difficult to manage On the relationship of sinusitis to infection of the tonsils and adenoids Mr CROOKS holds that broadly speaking such infection is not the common cause of sinusitis in childhood and that the removal of tonsils and adenoids neither prevents nor cures the condition He is less certain about the converse proposition and says that arguments both for and against sinusitis as a cause of infection of tonsils and adenoids can be deduced from his figures His own opinion is that sinusitis is a common cause of inflammation of the adenoids and to a lesser degree, of the tonsils

ANNOTATIONS

FOOD OF NEWCASTLE FAMILIES

Dr J A Charles, medical officer of health for Newcastle upon Tyne, is to be congratulated on a small but solid contribution to the science of nutrition made by his department in a report issued this week[1] In order to compare the diets of unemployed and employed families living in old houses or on new housing estates, the food purchased and consumed during a week by 69 families was recorded as faithfully as possible, allowance was even made for cats, dogs, and visitors, and all waste was weighed At the same time details were kept of income and expenditure Admittedly the numbers were small but in that admission lies the strength of the report The limitations of the data are fairly set out for the reader, and conclusions that are significant in a statistical sense are distinguished from the observations that are of other interest

The findings bear mainly on three questions Are the diets of the working class population adequate? What sort of job do the people make of feeding themselves on the means available? Does the higher rent of new housing estates influence nutrition? The amounts of food consumed varied widely, but the frequency distribution of diets according to calories, animal protein, and calcium content showed that more unemployed than employed fell below the range of intake within which sufficiency is held to lie The report is careful to point out that "it is not suggested that all diets below the ranges are necessarily inadequate for the families concerned but it is probable that such diets are within the danger zone in regard to the genesis of malnutrition" It also says that "it is very probable that the diets of the unemployed as a whole were inferior to those of the employed" The former bought 23 per cent more energy and protein per penny than did the latter but neither group showed "markedly excessive" purchase of expensive foods to the exclusion of equally nutritious cheaper foods These facts and the clear indication that most of the cooking, even of bread, was done at home speak well for the Newcastle housewife's ability Of course the families were not a true random sample, for selection of those who would collaborate was inevitable, but the investigators tried to make the selection representative and there is no reason to belittle the tribute As for the third question, rent was 21 per cent higher in the new housing estates than in the old houses, but it did not seem to be closely related to intake of food Another interesting finding was that the unemployed men weighed on the average 13 lb 4 oz less than the employed This difference, however, was not found among their families and the report suggests that perhaps these men lost their employment in the first instance wholly or partly because of poor physique, or that the loss of weight may have been due to wasting of muscle from lack of exercise The proportion of anæmic women was higher among the unemployed although no relation could be found between the hæmoglobin levels and the content of iron in the family diets The large families on the whole had less adequate diets and spent less money on food than the smaller families

The work described was carried out by a large team Mr A Bradford Hill D Sc of the London School of Hygiene, was responsible for the statistical aspect, Dr R A McCance and Miss Widdowson, of King's College Hospital, London, for some of the analyses, and the health department of Newcastle for the admirable report as a whole It should serve as a model for others of the same kind

CONGENITAL MULTIPLE POLYPOSIS OF THE COLON

It is fortunate that congenital multiple polyposis of the colon is a rare disease, for it places the physician or surgeon who diagnoses it in a most difficult situation The diagnosis is generally easy The patient, who is often young, usually complains of diarrhœa with or without blood in the stools, multiple adenomatous polyps, sessile or pedunculated, of any size up to 5 cm in diameter, may be felt with a finger in the rectum, seen through the sigmoidoscope, or recognised from the coarse mottling they produce in a radiogram of the colon filled with barium The condition is a precursor of malignancy, and death from carcinoma in some part of the colon or rectum often occurs in young adult life Five out of fifteen cases recently studied by McKenney[1] of Buffalo died in this way, the remainder were all between the ages of 2 and 20, and have a poor chance of surviving to middle life What treatment should be recommended to such patients? If the condition is already causing disabling symptoms, an operation involving risk may be more readily undertaken, but if the symptoms are still slight the likelihood of early death from malignancy at some uncertain date in the future has to be weighed against the risk of death as an immediate result of colectomy, for colectomy is the only means of removing potentially malignant tumours involving the whole extent of the colon It is an awkward responsibility, and becomes still more so when the patients' brothers and sisters are considered Though there has been argument as to whether the condition is strictly congenital (i e., present at birth), there is no doubt that it is hereditary and familial, and appears in early childhood McKenney's fifteen cases belong to two family groups, and several are children under 10 Should the siblings of a given patient be examined with the sigmoidoscope? On purely scientific grounds, yes, on immediate humanitarian grounds, perhaps no! Much depends on what prospect can be offered to a symptomless victim of his surviving colectomy with reasonable health McKenney suggests that the best surgical treatment is preliminary removal of all polypi from the lowest colon and rectum by fulguration, followed by resection of the rest of the colon and anastomosis of the ileum to the area denuded of polypi, which can thereafter be kept under observation for the detection of recurrence Thomas E Jones of Cleveland, discussing McKenney's paper, describes a patient so treated who was alive and well four years later Mayo and Wakefield[2] have described a modification of the same procedure, Soper[2] did something similar, using a snare instead of diathermy, with complete success 22 years ago McKenney also discusses X ray treatment, which he gave to as many as he could of his surviving patients He is satisfied that it causes both symptomatic improvement and a considerable reduction in the number of polypi More than that he is chary of claiming but even so much as that does something to make the horns of the doctor's dilemma less sharp confirmation of his findings as well as later reports of his cases would be very welcome Meanwhile where circumstances seem to contra indicate surgical treatment X ray treatment may be given with some hopefulness and it is surely justifiable to seek out unwitting subjects of the disease from among a patient's relatives and to give them at least the benefit of any good effect that radiation may have

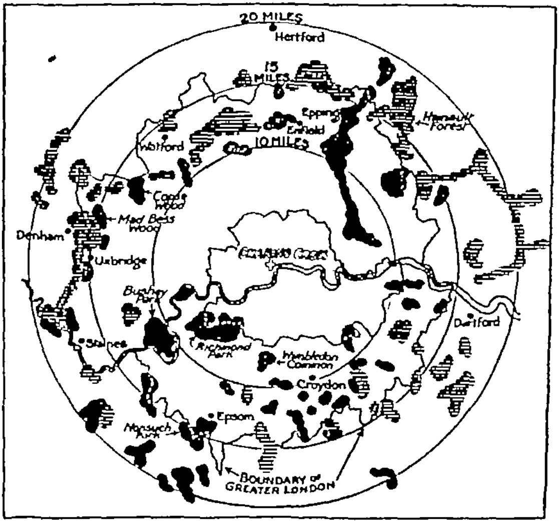
THE WORLD REQUIREMENTS OF NARCOTIC DRUGS

THE supervisory body established under the Drugs Limitation Convention of 1931 has assessed the world requirements of narcotic drugs for 1937 as follows morphine (including amounts used for conversion into other drugs such as heroin codeine and dionine) 40 976 kg against 45 978 in 1936 heroin 965 kg against 878 in 1936 codeine 25 724 kg against 30 598 in 1936; dionine 3199 kg against 3603 in 1936; and cocaine 4976 kg against 4924 in 1936 These estimates cover the requirements of 73 countries and 105 territories as well as 3 countries and 10 territories where there are customs unions or special administrative arrangements. In the case of 9 countries and 7 territories which failed to furnish figures the estimates were framed by the supervisory body The number of countries and territories failing to send in returns is, however decreasing year by year Moreover the estimates are annually approximating more nearly to the real needs Thus seventeen manufacturing countries had estimated for 1936 30½ tons of *morphine required for conversion* which was 65 per cent above the estimates for the same purpose in 1935 on representations being made by the supervisory body a reduction of 6¼ tons was effected in the morphine conversion estimates for 1937

The Permanent Central Opium Board at its last meeting with Mr Lyall (Great Britain) in the chair *called attention to certain discrepancies* between the recorded exports and imports of certain drugs Thus 73 tons of raw opium were reported as having been shipped from Iran to Straits Settlements but which appear to have been transhipped to Manchukuo whence no further information was forthcoming For the most part seizures of narcotic drugs are it is reported, becoming fewer and of less amount but this does not apply to cocaine and Indian hemp and it is suggested that addicts unable to obtain morphine and heroin are resorting to these drugs instead. While the legitimate use of heroin, according to the statistics is diminishing considerable quantities which had been seized had not been disposed of though some of it had apparently been converted into codeine

A GREEN BELT FOR LONDON

ALICE found it hard to distinguish whether Humpty Dumpty was wearing a cravat or a belt and serious people are now debating whether London is getting a belt or a cravat But no it is a belt. The time for having a cravat is long past with the days of the Restoration when Sir William Petty was imagining a circle of ground of 35 miles semi diameter round about the city from which London should get all her corn garden stuff fruits hay and timber and when John Evelyn was planning a phœnix London to rise from the ashes of the Great Fire plumed with gardens and perfumed with the scent of flowering shrubs However it was not to be London gave up wearing cravats and developed a *middle aged spread* and it is about her mature girth that the London *County Council* is putting a cincture and a handsome one too



[*By permission of the "Sunday Express"*

The scheme began in 1935 and under it the Council undertook to contribute anything up to half the approved cost of preserving land near London for open spaces but the councils of adjoining counties and boroughs were to be responsible for submitting proposals These proposals have reached the parks committee in a steady stream and 28 600 acres have already been acquired or provisionally approved for reservation The cost of preserving these lands is large and the Council has already engaged to contribute over £1 000 000 In time Londoners will have access to a belt of country which ranges from downland and wooded slopes to pasture and farmland stretching from Egham to Rickmansworth in the west towards Chipping Barnet and Epping Forest and southward from these to the north bank of the Thames near Rainham South of London the ring covers part of the North Downs in Kent and Surrey, and links up with Box Hill and Ranmore Common, finally sweeping round again towards Ankerwycke and Runnymede The belt is necessarily a broken one, or perhaps it would be fairer to call it a complete belt studded with these precious green medallions, which are now safeguarded for all time for the pleasure of Londoners The Council, with sober regard for the public purse, have tried to reserve as much land as possible at the lowest possible price, and have therefore proceeded with caution and reticence to avoid exciting the cupidity of land speculators But this is no reflection upon the owners of the areas purchased many of whom have shown great public spirit in reserving land for the green belt, as the Council gladly acknowledge

ŒSOPHAGEAL CANCER

No treatment yet devised for carcinoma of the œsophagus has proved effective, in fact the cases cured by any method are so few that they may be looked on as famous exceptions to the rule that this disease is at present incurable In such circumstances all new claims and reasonable proposals must be carefully considered. Especially welcome would be a form of treatment that would not tax the strength and endurance of an elderly patient much enfeebled by a wasting disease, and it is interesting to find Dr Ffrangcon Roberts[1] reporting tolerably good results from the use of deep X rays He begins his paper with a graphic description of the state of "withering undelight" of the wretched patient, goes on briefly to dismiss the alternative methods of treatment, and then describes his technique and the results obtained His plan is to irradiate the growth over a succession of strip fields, the rays being accurately directed from different angles so that the growth itself receives a maximum, and the surrounding tissues, especially the skin, a minimum dose He uses a large number of very narrow fields, thereby further concentrating the radiation on the growth Treatment is given on consecutive days, 3 fields a day and as many as 26 fields may be used in one patient The applicator is accurately centred and checked each time by means of an ingenious device whereby a tracing is made of the horizontal contour of the chest and the position of growth, and it is from this tracing that each position is precisely determined It is a pity that the results are recorded rather vaguely, there are no figures except in five illustrative cases Moreover, Dr Roberts excludes "advanced and debilitated cases" which seems hardly justifiable when a method is being considered which requires comparatively little endurance in the patient However, he is able to show one three year cure, and one patient alive and well fifteen months after the onset of symptoms, and it is to be hoped that the technique can yet be improved It may be noted here that Chevalier Jackson[2] considers X ray therapy, with or without gastrostomy, one of the best methods of treatment for œsophageal carcinoma and though radium has on the whole given disappointing results it is possible as Mailer suggests,[3] that a combination of radium and X ray treatment offers the best hope The most promising experience with radium is that of Guisez[4] but others have been less fortunate with it and most of the "cures" so far on record are those of radical surgery Torek's patient was alive and well twelve years after operation, and success has been achieved by a number of others including Eggers, Grey Turner, Kirschner, Ohsawa, and Abel In our present issue Mr Pilcher discusses radical excision of carcinoma of the cervical œsophagus, and describes a case of Trotter's which was free from recurrence ten years after operation, and in which the function of swallowing had been restored by plastic operation Such cases hold out hope for the future but until big advances have been made less heroic measures will still have an important place in the treatment of œsophageal carcinoma

THOUGHTS ON THE ADDENDUM

An ancient writer, commenting on the prescription of medicines with many ingredients, insinuated that its object was *pour faire valoir le metier* or *ad ostentationem artis* William Wadd, surgeon extraordinary to George II, in whose quaint memoirs this gibe is recalled, reflects that Bacon was perhaps nearer the truth when he said that the multiplicity of remedies was the child of ignorance—a thought that has often been expressed since though not always so happily Be that as it may, with the progress of science medicines have become more simple, and evidence of the trend will be found in the Addendum 1936 to the British Pharmacopœia 1932 It is not really very long since strychnine hydrochloride began to take the place of galenical preparations of nux vomica, and the alkaloids of opium began to be preferred to the tincture Sometimes it may be the whole drug is better than the active principle, but from the standpoint of the compilers of pharmacopœias the latter is certainly preferable, since a crystalline chemical product is capable of accurate standardisation The task of chemist and doctor alike grow easier when the abstract conception, vitamin C, comes down to earth as ascorbic acid or acidum ascorbicum

The Addendum has already been reviewed in The Lancet, but these second thoughts on the subject are prompted by the fact that since the beginning of the year its monographs have had the same authority as that of the B P itself

PREGNANCY ANÆMIA AND SOCIAL CIRCUMSTANCES

In the last few years increasing attention has been paid to the part played by poverty in the anæmia of pregnancy It was formerly thought that the anæmia arose from the demands of the fœtus for iron and other hæmopoietic principles, but recently as we noted not long ago,[1] Bethell[2] in the United States and Fullerton[3] in this country have suggested that pregnancy in itself is not a cause of it The iron saved by the cessation of menstruation, they calculate, makes up for the iron lost to the fœtus, though excessive hæmorrhage at delivery may of course be serious later, especially in women whose diet is deficient in minerals The high incidence of anæmia during pregnancy they attribute to causes not directly associated with the requirements of the fœtus

In an important study of pregnant women in Stockport, published in our last issue, Dr W J S Reid and Dr Jean Mackintosh bring forward additional data Among over 1100 women examined they found no case of hyperchromic anæmia, but

about 10 per cent had a hæmoglobin level below 70 per cent —a figure slightly lower than that given by J A Boycott for London and considerably lower than that found in a rather similar study in Aberdeen. In order to determine the effects of economic circumstance Reid and Mackintosh divided their patients into two groups according to the average income per head of the family after deduction of rent Group I contained women with an average income of 12*s* per head or less and Group II those with an income of over 12*s* a head (For this purpose the pregnant woman was counted as two) Of Group I 13 2 per cent had a hæmoglobin level of below 70 per cent a figure in closer agreement with the Aberdeen observations while of the higher income group *only 5 per cent had a low hæmoglobin* Multiparity even in good social circumstances began to have a definite effect on the incidence of anæmia when the women had had five or more pregnancies and in poor circumstances it affected hæmoglobin earlier in the childbearing career Only 7 6 per cent of primiparæ in Group I had anæmia but 15 4 per cent of multiparæ had a hæmoglobin below 70 per cent This is partly no doubt because when economic circumstances are bad it is almost always the mother who goes without Age apart from parity bore no relation to anæmia Women who worked outside the home during pregnancy decreased their liability to develop anæmia because they increased the family income

These observations show that undoubtedly pregnancy has an indirect effect in causing anæmia in women whose diet is inadequate The prevention of such anæmia in women and consequently in infants since its cause is recognised must be considered one of the major problems before any civilised community

DEVELOPMENTS AT LEEDS

SINCE the General Infirmary at Leeds was opened in the year 1869 extensions—and some of them very great ones—have been found necessary to meet the ever increasing demands made upon the institution. Sometimes it has even been thought that finality had been reached but this has always been found to be fallacious It has for long been felt that there ought to be in connexion with the Infirmary a paying department for the accommodation of those who are not in a position to meet the expense of the best nursing homes and yet are not of the recognised hospital class Greatly increased accommodation for the nursing staff which now numbers about 300 with an adequate recreation room and with better *provision for* the use of the *preliminary* school of instruction a new out patient department improved *accommodation for the X ray diagnostic department* and some structural alterations all appeared to be so important that in the year 1933 it was decided to make an appeal for the sum of £250 000 It is a matter for congratulation that on the last day of the year which has just closed it was announced that this sum had been reached During the three years since the appeal was launched much thought has been given to the plans in the case of the more urgent requirements the work has been going on and in some it has approached completion Not included in the £250 000 just mentioned there has come from Claire Lady Manton and her sons a welcome gift of £8000 for new buildings for the X ray diagnostic department which will enable the work to start at once Lord Manton took a deep interest in the work of the Infirmary and was on the Board for some sixteen years Along with Mr Charles Lupton he did much to improve the conditions of service for the nursing staff and when he made a generous donation of £50 000 to the funds of the Infirmary he stipulated that £10 000 should go to the nurses pension fund

A MINISTRY OF CHILDHOOD?

IT has long been recognised by teachers and parents that the human child if not a separate species is *pretty* well *a distinct variety* of *Homo sapiens* Mr Edward Fuller would have the Government recognise this fact and create a Department or Ministry of Childhood taking as its province all the needs of the child as specified in the Declaration of Geneva. Uruguay he tells us has such a ministry and Peru is about to create one while in this country the liaison between the Ministry of Health and the medical department of the Board of Education establishes what is virtually a national service for the supervision of the health of children from birth or before to school or after For fourteen years past the U S A. has had its Federal Children s Bureau dealing with every department of child welfare except education but Mr Fuller said that not many years ago in answer to an inquiry he received from one of the constituent States the reply We do not know what is meant by child welfare Speaking at the same conference which was arranged by the Nursery Schools Association Prof Olive Wheeler expressed her dissatisfaction at the over-emphasis of the legal aspect of delinquency by the Home Office behaviour that seems to her perfectly normal for the period of childhood—such acts as letting off fireworks in the street or riding bicycles without a light—are regarded by chief constables as offences leading to the taking of fingerprint impressions She would like the Board of Education to take on *more and more responsibility for the legal*, labour and health aspects of child life Both Dr G F McCleary and Dr Ralph Crowley were drawn into the discussion and Dr McCleary suggested the need for a million places in the nursery schools against the six thousand or so provided in the existing 78 schools His feeling was that if people wanted these schools enough they would see that they got them Dr Crowley was sympathetic to the idea of having a department at the centre always thinking of the whole child There were certainly enough ideas presented at the conference to keep the Nursery Schools Association going for another year

RECTAL ADMINISTRATION OF EVIPAN

HAVING found that rabbits and dogs readily absorb Evipan from the rectum in 10 per cent solution and are satisfactorily anæsthetised thereby Gwathmey[1] proceeded to use rectal evipan in his practice His object was to secure a perfect state of pre-anæsthetic unconsciousness on which true anæsthesia could be imposed with nitrous oxide ethylene and so on it was not intended that the evipan should be unaided a sufficient anæsthetic and in fact it sufficed by itself only for short and slight operations In the laboratory 50 mg per kg of body weight produced anæsthesia in animals five times out of six, unconsciousness lasting about an hour and a quarter The highest dose used 175 mg per kg, gave an anæsthesia lasting seventeen hours Dogs showed a wider margin of safety when evipan was given by rectal injection than when it was introduced by the vein The therapeutic index—that is the minimum [illegible] that dose divided by the minimal anæsthetic dose—was 4 rectally as against 3 3 intravenously At the time of his report Gwathmey's experience with human beings was limited to some 150 cases, but as far as it went it was very satisfactory Anæsthesia came on comfortably in about five minutes and there were no unpleasant consequences of the injection, either in the rectum or elsewhere A fairly large proportion of the patients during recovery showed the restlessness often seen after the action of a barbiturate, but pulse, respiration, and blood pressure remained normal unless upset by the surgeon The average dosage used was 0 2 c cm of an aqueous solution per pound of body weight (44 mg per kg), but physique, habits, and disposition of the patient were taken into consideration when determining the amount to be injected To the 10 per cent solution was added a quarter of a grain of morphia, but Gwathmey found that when Dilaudid was substituted for morphia there was much less nausea and vomiting after operation The use of other barbiturates in association with evipan he regards as inadvisable A further claim by Gwathmey is that rectal evipan brings freedom from pulmonary complications, but this is based on results with animals and appears unconvincing Moreover, as was pointed out by Dawkins in his treatise which we reviewed last week (p 35), the principal objection to premedication is its tendency to encourage lung trouble after operation unless it is managed with great care The technique of injection described by Gwathmey is laudably simple and the injection is given an hour before the time fixed for operation We are not aware of the rectal use of evipan hitherto in this country, but doubtless some will now be led to try it

---

ROUGH WEATHER IN BATTERSEA

UNDER the name of the Antivivisection Hospital, the Battersea Hospital was founded in 1902 as "a visible protest against the demoralising practice of performing any experiments on animals" A time came when the protest proved less and less emphatic, for want of funds, and eventually it was necessary to ask help from King Edward's Hospital Fund This help was not forthcoming so long as the institution maintained its original principles—principles that "somehow contrived to encourage moral condemnation of medical and surgical treatment elsewhere"[1] In this emergency Mr S E Parkes joined the board, provided financial guarantees, and became chairman An application was lodged with the Chancery Division for leave to eliminate the element of antivivisection from the name and objects of the Hospital and after the honorary medical superintendent Mr J R Lee, F R C S, had testified that the progress of science and advance in knowledge made it nowadays impossible to run a general hospital on antivivisection principles the Court accepted the plea and the Battersea General Hospital started on a new lease of life King Edward's Fund made a grant and money was collected, but the question then arose whether the Hospital should not fall into line with others of its kind in its manner of making staff appointments, none of which had so far been the result of open competition In December, 1935 the members of the staff were invited (and all except two agreed) to sign a statement that their posts were terminable by the Hospital at the end of each year, and last autumn notice was given that all of them would in fact be terminated at the end of 1936 and advertised in the medical press—though in making new appointments preference would be given, other things being equal, to the former holders Mr Parkes asked the help of the British Medical Association, and a selection committee, including the dean and the professors of medicine and surgery at the British Postgraduate Medical School, was set up to consider the applications. Nearly all the former staff applied for reappointment, but many of the places were filled by candidates from outside Some of those who failed to secure reappointment held that they had been unfairly treated and have accordingly applied for, and obtained, an injunction restraining the Hospital from their dismissal before their case can be heard They may argue perhaps that they signed the statement about annual tenure on the assumption that it would apply, as at other hospitals, only in exceptional circumstances, they may say that reasonable security is essential for the honorary hospital officer Meanwhile a crisis has arisen over the position of Mr Lee, the senior surgeon, who was not reappointed —but (we understand) took no legal action Mr Lee is approaching the age of retirement under the new regulations, and the selection committee may have preferred to bring in a younger man, but he has done fine work in steering a course towards a new and better state of things, and when it came to the point last week the hospital board could not bring themselves to drop the pilot Mr Parkes, whose services as chairman of the board have also been invaluable in the past year or two, unfortunately felt bound to regard this as a vote of no confidence in himself, for he held that the views of the selection committee must be accepted or rejected as a whole. So he resigned, and two other members of the board with him This is clearly regrettable, and it is to be hoped that a way will yet be found to resolve the conflict of loyalties

WE regret to announce the death on Sunday last in a London nursing home of Dr D F Fraser Harris in his seventieth year Quite early in his career he took the Neil Arnott prize in physiological physics which remained a major interest to him throughout his life After taking very high qualifications in science as well as in medicine, he taught physiology at Glasgow and acted as professor of physiology at St Andrews until he was called in 1911 to the chair of physiology at Dalhousie, Nova Scotia, where he remained until 1924 He had a gift for clear and graphic exposition and his popular books on physiology have had a wide circulation.

THE SPANISH MEDICAL AID COMMITTEE—This Committee has presented to the Spanish Government the hospital that the British Medical Aid Unit established at Grañen (see Mr Sinclair Loutit's letter published in our issue of Nov 28th), and members of the medical staff have gone to Albacete to work with the International Brigade there The hospital at Grañen is now being run by the Spanish authorities but at their special request the British nurses are staying on The standard of nursing in Spain is low and the Spaniards have been much impressed by the skill and efficiency of the English nurses. Doctors nurses, and drivers sent out by the Spanish Medical Aid Committee will in future go to the International Brigade at Albacete Last week the Committee sent out a Talbot ambulance, similar to those used by the London County Council and two more will go during the next week or so together with a lorry full of medical and surgical supplies A special decontamination van is also being dispatched to Madrid to deal with people who have been affected by mustard gas

PRINCIPLES OF MEDICAL STATISTICS

II.—SELECTION

IN medical statistics we are nearly always working with samples drawn from large populations. For instance, if we compare the mortality of diabetics treated with insulin with diabetics not treated with insulin we do not possess information regarding all such persons (whom we may term the "universe" of diabetics) but only for a sample of each type which has come under our own observation or under the observation of others. If we wish to argue from this sample to the universe from which it was drawn, to deduce that what is true of our sample of patients is therefore true of the general run of patients, then we must consider very carefully whether in fact our sample is fully representative of all patients and not in any way biased or "selected." It is important to be clear on the meaning the statistician attaches to the word selected. By a selected sample he denotes a sample which is not representative of the universe from which it is drawn. The selection may have been deliberate, in which case the form of selection is known and the lack of comparability between the sample and the universe is usually perfectly clear. For instance, if the treatment of respiratory tuberculosis by means of artificial pneumothorax is confined in a sanatorium to patients with signs of disease in one lung only then it is obvious that these patients are *not* a representative sample of all patients with phthisis but are selected on the criterion of one lung only affected. To compare their mortality experience with *that of all patients is therefore* a very doubtful procedure, for we are clearly not comparing like with like in all respects except artificial pneumothorax treatment. Even without that treatment the death-rate of patients with only one lung affected may differ materially from the death-rate of the general run of patients.

More often, however, the "selection" is not deliberate but is quite unforeseen or is unrealised. To say, therefore, that Mr. So-and-So's figures relate to a selected sample of patients is not an aspersion on Mr. So-and-So's scientific honesty; the statement implies only that owing to the method of collection of the figures or to the limited field in which Mr. So-and-So was able to operate it is quite impossible for his sample to be representative. It may be that with care that selection might have been avoided; often it is unavoidable. Its possible presence cannot be too carefully remembered or taken into account in interpreting statistics. As, however, it is frequently overlooked a series of examples will not be amiss.

Examples of Selection

I

As a simple illustration I have taken from the *Times* the frequency with which male and female births are recorded in the birth column. In 1935 the number of male births was 3304 and female births 3034, so that the sex ratio is 1089 males for each 1000 females. According to the Registrar-General's figures for England and Wales the sex ratio of births in the country as a whole rarely exceeds 1050. It is clear that from the point of view of sex ratio the births recorded in the *Times* are not representative of the births in the country as a whole. It is possible that first births are more frequently recorded *in those columns than births of a later order* and that such births have a different sex ratio; or that proud parents are more likely to record their heirs than their daughters; or that the sex ratio differs between social classes. With such a sample of births, if that was all that was available, one could not generalise about the universe with any security.

II

Hospital statistics can very rarely be regarded as unselected. The patients are frequently drawn from particular areas and largely from particular social classes. Still more important, in many diseases only those patients who are seriously ill are likely to be taken to hospital. It is obvious that we cannot determine with any approach to accuracy the fatality-rate of any disease, say measles at ages 0–5 years, if our statistics are based only upon the seriously ill—perhaps only upon patients in whom a secondary pneumonia has developed—and ignore the mass of children whose symptoms are so slight that they can safely be treated in their own homes. Of *all* children with measles those in hospital will often form only a small and stringently selected group; our deductions from such a group are correspondingly limited, especially with regard to such factors as the incidence of complications and the rate of fatality or recovery. It is not too much to say that there is no disease in which a hospital population must not initially be regarded with suspicion if it is desired to argue from the sample to the universe of all patients. No such argument should be attempted without a preliminary *and rigorous examination of the possible ways in* which selection may have occurred.

The same difficulty arises with secular comparisons—e.g., when we wish to see whether the fatality from some disease has changed from one year to another. In each year the fatality-rate is measured upon the patients admitted to hospital and in each year those patients are a sample of all patients with the disease in question. It must be considered whether that sample has changed in type. In both years the sample may be a selected sample but the selection may not be identical. The kind of patient admitted may have changed. For example, in a group of American hospitals it has been reported that the fatality-rate from appendicitis declined from 6 per cent. in 1928 to 3.5 per cent. in 1932. Is that a "real" decline or has there been a concurrent change in the types of patients admitted? Examination of the basic figures shows that in these hospitals in 1928 some 2500 patients were operated upon while in 1932 the number had risen to 3500, an increase of 40 per cent. It is impossible to believe that an increase of 40 per cent. in five years is a real increase in the incidence of appendicitis. It is more likely that the desire for admission to these hospitals or the criteria of admission have changed; that some patients who were admitted in 1932 would not have entered them in 1928. It is possible therefore that the type of entry has changed as well as the volume—perhaps that milder cases were admitted and operated upon in 1932 which were not present in the 1928 series. In the absence of positive evidence on that point the change in fatality cannot be accepted at its face value or as satisfactory evidence of the effect of a change in some other factor—e.g., the benefit of earlier admission to hospital in 1932 than in 1928. The following two questions must always be considered. Has there been a change in the population from which the samples are drawn at two dates—i.e., a change relevant to the question at issue? At each date was there an equal probability that a particular type of patient would be included in the sample?

III

In measurements of the value of some form of treatment, statistics of the following type are frequently given —

Day of disease upon which treatment was first given	Fatality rate per cent of treated patients	Day of disease upon which treatment was first given	Fatality rate per cent of treated patients
1	1 3	4	9 3
2	3 6	5	12 8
3	7 5	6 or later	16 4

It is possible that the level of this fatality rate at the different stages is seriously influenced by selection Let us suppose, as is often the case, that the treatment is given to patients brought to hospital and that *all* patients do not necessarily go to hospital Then on the first day of disease a variety of patients will be taken to hospital, in some of whom, in the absence of the special treatment, the disease is destined to run a mild course, in others a severe course The presence of a proportion of mild cases will ensure a relatively low fatality rate, even if the special treatment has no specific effect But as time passes this proportion of mild cases in the hospital sample is likely to decline By the time, say, the fourth day of disease is reached a number of patients who were not seriously ill will have recovered or be on the way to recovery Their removal to hospital is unnecessary On the other hand, patients who have made a turn for the worse or whose condition has become serious are likely to be taken to hospital for immediate treatment Thus on the later days of disease the sample removed to hospital for treatment is likely to contain an increasing proportion of persons seriously ill it obviously being unnecessary to transfer those who are making an uninterrupted recovery In other words the patients removed to hospital on the fourth day of disease are not a random sample of all patients who have reached that day of the disease but consist rather, perhaps mainly, of patients still seriously ill Such a group will certainly have a relatively high fatality rate

Another example of this statistical difficulty may be taken from some fatality rates recorded for appendicitis It has been reported that in a group of cases 2 per cent died of those admitted to hospital within 24 hours of the onset of symptoms compared with 10 per cent of those whose admission was delayed till after 72 hours But it is likely that the group of patients admitted early is composed of a proportion of the seriously ill and a proportion that would do well whether admitted to hospital or not On the other hand those who are admitted after a delay of three days from onset are likely to be patients whose condition is serious, and clearly those whose condition has become quiescent are unlikely to be taken to hospital at that point of time If such a sequence of events occurs, it is clear that the group of patients admitted early is not in pari materia with the group of patients admitted late Selection may not be the whole explanation of the difference between the fatality rates, indeed it is not likely to be for there are excellent reasons for the early treatment of appendicitis But it is a possible factor with statistics such as these which makes it very difficult to measure accurately the *magnitude* of the advantage

IV

A sample which is composed of volunteers or self selected individuals is not likely to be a random sample of the universe from which it is drawn. If, for example, the treatment of colds by vaccine is offered to a group of persons, the volunteers are likely to belong mainly to that section of the group which suffers most severely from colds and hopes for some advantage from the treatment They are in that event a select group, not comparable with the remainder of the population from which they were drawn In such cases the question must always arise is the act of volunteering correlated with any factor which may have an influence upon the final results of the experiment?

Self-selection

An interesting example of what may be termed self selection is worth quoting In 1931 the Industrial Pulmonary Diseases Committee of the Medical Research Council wished to make an inquiry into whether the working health and capacity of coal miners are impaired by the inhalation of anthracite dust To begin with, a study was made of the size and age constitution of the working population at the South Wales anthracite collieries Underground workers had to be excluded from the investigation, since such workers as well as being exposed to various concentrations of anthracite dust in the atmosphere may in addition be exposed at times to silica dust. If the health of these workers was found to be impaired it would be impossible to implicate anthracite dust as the responsible agent The impairment might equally well be due to exposure to stone dust containing silica, which, it is well known, can produce serious damage to health In addition it was considered necessary to exclude surface workers who had at any time worked underground, since the effects of exposure to silica dust will not necessarily be immediately apparent and also because impaired health may have been the reason for transference from underground to surface work This was, in fact, known to be the reason in numerous cases, so that such workers would be a highly select group Attention was therefore turned to workers who were exposed to anthracite dust on the surface and had *always* worked on the surface Such workers, it was found, are employed on a relatively light task Not only was there a tendency to draft to it operatives who had previously worked underground and had for one reason or another become partially incapacitated but in addition it was clear that a large number of boys were initially employed upon this work but rapidly moved away to other work In the main these boys were drafted underground where the physical labour was heavier but the rate of pay superior

The inevitable inference is that the healthy and strong individuals will transfer to underground work while those who remain on the surface are likely to be of under average physique and health In other words there has been a form of self selection If the examination of such surface workers showed that they included a high proportion with impaired health or that they suffered an unduly high rate of sickness in comparison with some standard, this result could not with security be ascribed to the effects of dust inhalation It might be considerably influenced by the fact that these surface workers were, through the operation of selection, initially less healthy than a random sample of all surface workers This investigation also contains an example of selection through volunteers being accepted for examination For the reasons outlined above no inquiry was made at the collieries and the field of study was transferred to dock workers exposed to anthracite dust Of 250 such workers it was arranged to examine clinically and radiologically a sample of 40 operatives—namely 15 workers employed for only 3–4 years and 25 older workers with 15–40 years service. These two groups were selected at random from the complete list of operatives, to ensure as far as possible with such small numbers a representative sample At the examination eleven of these men were absent and to make good the deficiency in numbers volunteers were secured in place of the absentees

The results of the examinations suggested that there was a readiness to volunteer on the part of individuals who on account of some known or suspected disability desired to be medically examined Such substitutions may therefore result in the sample ceasing to be random and representative of the population from which it was drawn

Questionnaires

Inquiries carried out by means of questionnaires are par excellence those in which selection must be suspected In all such inquiries replies to the questions put—even to the simplest question—are received from only a proportion of the individuals to whom the form is sent There can never be the slightest certainty that the individuals who choose to reply are a representative sample of all the individuals approached indeed very often it is extremely unlikely that they are representative For example one *may take the inquiry made by the Editor of* THE LANCET into the Present-day Openings of Medical Practice (*Lancet* 1935 2 512) To measure the success with which recent graduates had been attended in their profession a questionnaire of three relatively simple questions was addressed to the 1490 men and women who in 1030 registered their names with the General Medical Council viz (1) What branch of medicine have you taken up ? (2) What led you to this choice ? and (3) What was your approximate income from professional work last year ? To overcome objections to providing such personal information no clue to the identity of the correspondent was required Of the individuals approached 44 per cent replied Are these persons a representative sample of the 1490 ? It is possible as is clearly pointed out in the report that there might be a tendency for those who have been successful in their profession to be more eager to register their success than for those who have failed to register their failure Alternatively the latter might under the veil of secrecy be glad of the opportunity of stating frankly the drawbacks of the profession Those who have turned to other professions might tend not to reply under the impression that the inquiry cannot concern them Successful and busy individuals might be unwilling to give time to the inquiry *It is impossible to determine whether any* such factors are operative in the determination to answer or not to answer The difficulty is inherent in all inquiries carried out by this method

House Sampling

An interesting example of selection in taking a random sample of houses is suggested in the Ministry of Health's report on the influenza pandemic of 1918 (Reports on Public Health and Medical Subjects No 4) To obtain facts as to the incidence and fatality from influenza in 1918–19 a house to house inquiry was undertaken in five areas of Leicester information being obtained *so far as possible* at every fifth house Houses which were found closed at the time of visit had to be ignored in this census But houses in which there are young children are rarely found closed and this would tend to affect the age distribution of the population recorded in the sample Compared with the population from which it was drawn the sample would be likely to contain an undue proportion of young children and a deficit in the number of adults Any substitution of another house for the original randomly chosen one would be likely to add still further bias to the sample and such substitutions are to be avoided in sampling inquiries

It will be noted that a selection of this type would be difficult to foresee It is here that the statistician has some advantage for his experience of such inquiries makes him familiar with the methods that are likely to ensure a random sample and those that are likely to lead to one that is unrepresentative of the population from which it is taken Workers who are unfamiliar with sampling inquiries but wish to embark upon one may therefore find his advice of assistance

Summary

In statistics we are working nearly always with relatively small samples drawn from large populations to be in a position to generalise the sample *must be representative of the population to which* it belongs In taking samples selection may occur through the operation of various factors A selected sample is one which is not representative of the universe whether the bias be due to deliberate choice or unconscious selection of the members incorporated in the sample In generalising from a sample or in making comparisons between one sample and another the possible presence of selection must always be very closely considered

A B H

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED *DEC 20TH 1030*

Notifications—The following cases of infectious disease were notified during the week: Small pox, 0 scarlet fever 1036; diphtheria, 1013; enteric fever 21; pneumonia (primary or influenzal) 832 puerperal fever 22 puerperal pyrexia 72; cerebro-spinal fever 10 acute poliomyelitis, 3 encephalitis lethargica 4 dysentery 10 ophthalmia neonatorum 40 No case of cholera plague or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Jan 1 1937 was 3151 which included: Scarlet fever 999; diphtheria 1060; *measles* 10 whooping-cough 1 7 puerperal fever 14 mothers (plus 9 babies) encephalitis lethargica 255 poliomyelitis 4 At St Margaret's Hospital there were 12 babies (plus 5 mothers) with ophthalmia neonatorum

Deaths—In 122 great towns including London, there was no death from small pox 2 (0) from enteric fever 1 (0) from measles, 2 (0) from scarlet fever 11 (1) from whooping-cough 10 (7) from diphtheria 33 (8) from diarrhoea and enteritis under two years and 0[illegible] (2[illegible]) from influenza The figures in parentheses are those for London itself

Sheffield and Stockton-on-Tees each reported a death from enteric fever Thurrock [illegible] death from whooping-cough Fatal cases of diphtheria were reported from 15 great towns Liverpool 6 Thurrock 4 Bradford and Manchester each 3

The number of stillbirths notified during the week was [illegible]20 (corresponding to a rate of 40 per 10[illegible] total births) including [illegible]3 in London.

MODERN VIEWS ON INFECTION AND DISINFECTION *

BY SIR WELDON DALRYMPLE CHAMPNEYS, Bt.,
M.D. Oxon., F.R.C.P. Lond.
A MEDICAL OFFICER AT THE MINISTRY OF HEALTH, LONDON

A GENERAL overhaul of our methods of preventing and treating infectious diseases in the light of modern knowledge is long overdue, and reform in this sphere—as ultimately in every sphere of public health work—depends upon the existence of an enlightened public opinion. On no subject perhaps has thinking been looser and generalisation more irresponsible than on that of infectious diseases, and the time has come when clear thought and scientific assessment are essential if we are to make full use of the mass of valuable knowledge accumulated by research workers in recent years. I must content myself with calling your attention to certain selected aspects.

Infection

THE NATURE OF INFECTIOUS DISEASE

We are apt, I think, to picture the life of man as an originally idyllic existence, which at some very remote period and for some very obscure reason (associated perhaps with apples) was suddenly interrupted by the invasion of some ill-natured creatures called microbes which had the nasty habit of causing disease in their host man. But if we consider the matter for a moment it is plain that the pathogenic or disease-producing micro-organisms are some of the simplest and therefore most primitive living things upon this earth and must, though doubtless in a slightly different guise, have been in existence long before man appeared upon the earth. Whether these organisms took to a life of crime before or after man had evolved as a separate genus is really an academic question, and we can be sure that, speaking generally, the fight between man and his parasites (for all disease germs can be so described) has been going on throughout man's history. Microbial disease—to use an old but convenient term—can in fact be defined as a disturbance of health in man or other living things due to the presence of parasitic organisms, or in other words as a disturbance of the equilibrium between host and parasite unfavourable to the host. Bordet (1920) has expressed this with the neatness so characteristic of his race: "La vie est le maintien d'un équilibre incessamment menacé." Every addition to our knowledge of infection and immunity serves to emphasise the incessant nature of this menace and there can be no doubt that, as Andrewes pointed out, the constant struggle of man against disease must have played a most important, though much neglected, rôle in our evolution. "Of all the teeth in the terrible comb with which Nature sorts out the inefficient," he writes, "disease is one of the most formidable."

In order that the host should survive these incessant attacks he must of course become adapted in some way to the parasite—just as the parasite to survive the attacks of the host's defensive mechanisms must also become adapted—and to watch the parasite's attacks persistent but never carried so far as to exterminate the host species, which would involve its own extinction, is to be reminded inevitably of a cunning blackmailer at work.

Of the many different micro-organisms which may be found in the human body not all are harmful and some are even useful to us. Moreover it is important to remember that the discovery in the body of a micro-organism capable of causing a disease does not necessarily mean that the patient is suffering from the disease in question or even that they have been recently infected. We all of us, in fact, like the great nobles of past centuries, support a large number of dependants of whose presence we are hardly if at all aware. I shall refer again to this curious phenomenon, the importance of which is only beginning to be realised, when dealing with so-called "carriers," but I must refer for a moment to the difficulties attending the definition of "infection."

It is obviously confusing to use the same word to express the successful attempt of a pathogenic micro-organism to penetrate the first line of defence and establish itself in the body of its host, and also the further success by which it produces a definite disturbance of health or a disease. In my opinion no completely satisfactory solution of this difficulty has been found, but the terms "infection" for the initial success and "invasion" for the further one are widely used and have a certain amount to recommend them.

THE REACTIONS OF THE HOST TO THE PARASITE OR ITS PRODUCTS

The reactions of any host to the presence of a pathogenic organism are numerous and complex, and although our knowledge of these reactions has been greatly extended in recent years it seems probable that we have so far explored only the fringes of this mysterious territory. I shall therefore make no attempt to give a complete account of these reactions but will merely mention those which seem to be the most important. Naturally these reactions are not mutually exclusive and several often occur successively or simultaneously in the same host (see Diagram).

1. The parasite may be killed immediately by the defensive mechanisms, specific and non-specific, of the host's body, without the manifestation of any signs or symptoms of disease.

2. The parasite may give rise to the local reaction known as inflammation, which may or may not be accompanied by—

3. Pus formation, pus consisting mostly of the dead bodies of the white blood corpuscles killed by the parasite whilst defending the host.

4. The parts immediately surrounding the site of infection may die—i.e., local necrosis may occur.

5. Fever may result. This is a protective reaction of the host as the raising of the body temperature increases, in some way at present little understood, the efficiency of some or all of the body's defensive mechanisms. Artificial fever has been used for many years in the cure of microbial disease, having been usually produced by means of so-called "protein shock" (by the injection of milk, a vaccine made from the causative organisms of a different disease, &c.), but recently the production of artificial fever by the actual mechanical heating of the whole body to a high temperature for a short time has been tried, apparently with considerable success.

6. The body of the host may respond to the stimulus of the parasite's presence by the formation of substances known as "antibodies." These antibodies are of many different kinds, new varieties being constantly discovered

---

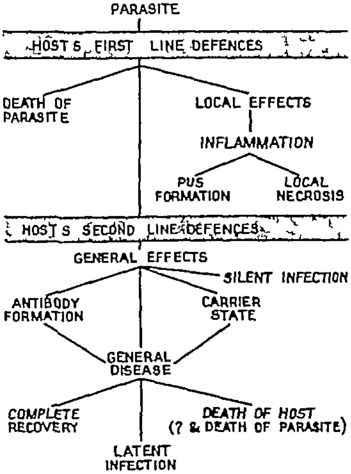
* The substance of a Chadwick lecture delivered on Dec. 9th.

and probably many are still unknown, but those which are produced as a reaction to the presence of a parasite (or more accurately speaking to the presence of a specific substance or "antigen" liberated by the parasite during its life or after its death) are specially adapted to destroy precipitate or otherwise put out of action the parasite in question.

7 The parasite may succeed in producing a disturbance of health or disease in the host with or without fever and this disease may terminate in one of three ways (*a*) complete recovery with destruction of the invading parasite (*b*) apparent recovery but with survival of the invader (*c*) death of the host—and nearly always of the *parasite too*

8 The parasite may establish itself in the body of the host without causing any disturbance of his health but there is always or nearly always some reaction to the parasite's presence such as antibody formation, though such a reaction may be difficult to detect in these so-called "silent infections" Silent infections result in the host acquiring immunity to the particular parasite as in tuberculosis diphtheria, scarlet fever &c This immunity can sometimes be demonstrated by a skin test depending on the sensitivity to a toxin or poison of the particular parasite acquired by the skin as the result of a previous infection

9 A carrier state may be established in connexion with either of the last two reactions to which I have referred, that is to say either as the result of a definite illness followed by apparent recovery without complete destruction of the invading parasite or in consequence of a silent infection. I shall refer later to the importance of this carrier state in the spread and treatment of infectious diseases. It consists essentially in the presence of a parasite capable of causing disease without the actual occurrence of such disease



Before leaving this question of the reaction of the host to the parasite I would call attention to the fact that a disease (and I am here referring to an infectious disease) is not to be conceived of as the reaction of a host to the invasion of one particular parasite but as a frequently recurring and well-defined complex of signs and symptoms which may be produced by the attack of one or more of a number of quite different micro-organisms as is the case in pneumonia dysentery meningitis enteric fever &c

CHANNELS OF INFECTION

Infecting parasites may enter the body through a number of different portals, but I propose to consider only the two commonest—viz., the skin and the nose and mouth

Through the skin.—Invasion may result either in a local injury or lesion (with or without constitutional disturbance) or in generalised disease without local manifestations. Examples of local lesions caused by infecting micro-organisms are boils due to the staphylococcus and malignant pustule due to the *Bacillus anthracis* Infections through the skin resulting in general disease are syphilis due to the *Treponema pallidum* bubonic plague due to the *Bacterium pestis* transmitted by the flea leprosy due to the *Bacillus lepræ* undulant fever due to one of the organisms of the brucella group malaria due to sporozoa transmitted by the mosquito yellow fever due to a virus transmitted by another mosquito typhus due to a virus transmitted by the body louse sleeping sickness due to a trypanosome transmitted by the tsetse fly and Rocky Mountain spotted fever due to a rickettsia transmitted by a tick

Through the nose and mouth.—There are two main ways in which infection may enter—i e either by the inhalation of infected droplets in the breath of patients or carriers, or by swallowing infected food or drink Examples of droplet infections are measles whooping-cough influenza the common cold cerebrospinal (spotted) fever pneumonic plague scarlet fever infectious sore throat or tonsillitis pulmonary tuberculosis diphtheria small pox chicken pox mumps and German measles Examples of disease caused by micro-organisms contained in food or drink are bone and joint tuberculosis due to the bovine tubercle bacillus often present in milk cholera typhoid and paratyphoid fever undulant fever due to milk infected with the *Brucella abortus* which causes contagious abortion in cattle and infantile diarrhœa I may call attention in passing to the rôle played by flies in the transmission of some diseases in this group clean food often being contaminated by these insects settling upon it after visits elsewhere

Changed Views on Infection

Let us now consider in what respects the knowledge accumulated in recent years has changed our views with regard to infection and infectious diseases There is space only to discuss a few aspects of this question so I will choose those which seem to be of the greatest interest not only to the medical profession but to the public in general.

MODE OF INFECTION IN VARIOUS DISEASES

The first example is cholera the disease which took such a terrible toll of the population of London and other large towns in Chadwick's day and the prevalence of which was influenced more than that of any other perhaps by the environmental reforms which he initiated Though Chadwick was wrong in attributing the propagation of cholera to atmospheric impurities he was right in connecting its prevalence with the appallingly filthy conditions under which the working classes in our large towns then lived and in insisting upon efficient drainage street cleaning and the provision of a good water-supply as the chief means of combating this and many other diseases then prevalent We know now that cholera is spread chiefly by water and food contaminated with the specific vibrio rather than by "atmospheric impurity" or an "epidemic atmosphere" but if "atmospheric impurity" can be taken to cover infected droplets then he was right about the method of spread of many common epidemic diseases other than cholera and his demand for better ventilation and the abolition of overcrowding for the prevention of these diseases

Malaria is another disease which used to be attributed to the peculiar constitution of the air in certain places—usually referred to as a "miasma," as the "ague" (as it was formerly called) was known to be prevalent chiefly in damp and marshy places where mists were common The story of the mosquito's incrimination and the proof that it conveyed the causative parasite to man by its bite has often been told and is familiar to all, but no one who has investigated a great malaria epidemic would pretend that all the factors operating in the spread of the disease are yet understood

In the case of scarlet fever the change in our views has been not so much in the direction of rejecting one channel of infection in favour of another, as in a changed estimation of the importance of the various infection mechanisms which may operate, the discovery of the important rôle played by carriers, and the recognition of a number of other diseases or conditions as due to the same micro-organism and therefore capable of being caused by infection from patients suffering from other diseases of the same group Not many years ago the infection in scarlet fever was believed to be conveyed chiefly by direct contact with the patient, his clothes, the books which he read, the flakes of skin shed from his body during "peeling," &c Nowadays, however, though we still recognise the dangers of direct contact, we know that infected droplets in the breath of a patient—not only of a scarlet fever patient but of certain persons suffering from tonsillitis, sore throat, rheumatic fever and puerperal fever, or of the carrier of a hæmolytic streptococcus—are the chief sources of danger to others

Our views about the spread of diphtheria have changed still more in recent years, but I have been astonished to find that the old idea of this disease being contracted from "bad drains" still persists even among educated people Droplet infection is, of course, the chief method of spread in diphtheria, and though the causative organism *Corynebacterium diphtheriæ*, commonly known as the Klebs Löffler bacillus, can be conveyed by direct contact, this mode of transmission is probably less common even than in scarlet fever

THE RÔLE OF CARRIERS

No discovery, perhaps, since the "germ theory" was established has shed greater light on the epidemiology of infectious diseases than the demonstration of the carrier state The origin and distribution of many epidemics of diphtheria scarlet fever, tonsillitis cerebro spinal meningitis, &c, were in fact quite inexplicable until it was shown that healthy persons often harbour the causative organisms of these diseases in their noses and throats whilst the gall bladders of other persons may harbour the typhoid bacillus in the same way, leading to excretion of the organism in the stools and so to the contamination of food &c handled by the infected but healthy carrier A transient carrier state is probably extremely common but the condition may persist for many years and be most intractable to treatment

DIFFERENT "DISEASES" DUE TO THE SAME ORGANISM

I have already remarked upon the fact that a disease is a clinical not a bacteriological entity and that the same disease, or complex of signs and symptoms, may be due to infection by a variety of different organisms The converse may, however, also be the case—i e, a number of different diseases may be due to infection by the same micro-organism. Perhaps the most striking illustration of this truth—or at any rate one of the most important from the practical point of view—is afforded by the group of diseases and conditions due to infection with various hæmolytic streptococci This group includes scarlet fever, streptococcal tonsillitis and epidemic sore throat, puerperal fever, and probably acute rheumatism commonly known as "rheumatic fever"

The connexion between scarlet fever and puerperal fever has been suspected for at least a century and has been the subject of hot and sometimes acrimonious debate Although suspicion was aroused by the occasional occurrence of cases of puerperal fever in the practice of a nurse midwife who had been attending a case of scarlet fever or had been accidentally in contact with one, proof of the connexion was impossible until the causative organism in the cases of each disease had been shown by modern methods of bacterial typing to be identical and the origin of many cases of puerperal fever due to the hæmolytic streptococcus was difficult to explain before the existence of the carrier state was recognised

Puerperal sepsis, which accounted for 1006 deaths in this country in 1935, has been and still is one of the hardest problems of preventive medicine, but recent work by White (1936) and others at Queen Charlotte's Hospital has shown how difficult it is to rid a room occupied by a puerperal fever patient of the specific organism, and the infection of women recently delivered, by hæmolytic streptococci carried in the noses and throats of those attending them is also well established It is hoped that the precautions indicated by this recent work may lead to a great reduction in the future incidence of the disease

The demonstration that cases of acute rheumatism and scarlet fever may result from the presence in a community of cases of streptococcal tonsillitis or epidemic sore throat has resulted chiefly from work in schools in this country and America and has thrown a flood of light upon the epidemiology of these diseases Scarlet fever, which has always hitherto been regarded as a highly specific disease, is now recognised to be merely one of several ways in which the body may react to infection with a hæmolytic streptococcus A pin point, flat red rash of a certain distribution is characteristic of scarlet fever (though such a rash is not peculiar to this disease), but a patient with scarlet fever showing this sign may give rise to a case without this rash but with every other sign and symptom of the infecting case This discovery is, naturally, of the greatest importance for the control of scarlet fever and the associated diseases Okell and Elliott (1936) and Garrod (1936) have recently described the occurrence of cases of scarlet fever in the ear, nose, and throat wards of two large general hospitals in London, which could not be traced to infection from any definite primary case of scarlet fever but became explicable at once when swabs were taken from the throats of the patients and the staff of the wards and the hæmolytic streptococci grown from these swabs were typed In the case of rheumatic fever we are not at present quite so sure of our ground, for though it seems almost certain that hæmolytic streptococci which may have been acquired from a patient suffering from scarlet fever or epidemic sore throat play a definite part in the production of this disease it seems possible that an ultramicroscopic virus may also be concerned

CROSS INFECTION WITH DIFFERENT STRAINS OF THE SAME ORGANISM

Another discovery of the greatest practical importance that has been made in recent years chiefly in connexion with the group of hæmolytic streptococcal diseases is that there are numbers of clear cut types of some kinds of micro-organisms and the limitation of immunity to reinfection to the particular type *causing the infection I cannot here discuss the very* difficult subject of immunity but it is necessary to refer to one or two of the phenomena of immunity in order to make clear the phenomena with which I am now dealing Different micro-organisms vary very much in the degree of immunity which they excite in their host Some give rise to only a *temporary immunity* to reinfection by the same organism which persists only so long as the living parasite is present in the host s body This is the type of immunity found in syphilis, tuberculosis malaria trypanosomiasis piroplasmosis and probably undulant fever and what Edmond Sergent and Parrot (1935) have christened prémunition Other parasites give rise *to a more lasting immunity* which may gradually fade away or may be life long as in measles typhus typhoid yellow fever small pox, chicken pox hydrophobia plague and anthrax

This acquired immunity (in contradistinction to inherited immunity) is highly specific but again its specificity varies Thus the immunity acquired as the result of infection by a particular parasite may give protection against all types within the parasitic species or only against the particular type which has caused the infection The latter narrow specificity is unfortunately characteristic of the hæmolytic streptococci and this fact is of the greatest practical significance as it means that a patient suffering from a disease or condition due to this organism may acquire an added infection due to a different type of the same organism from another patient suffering from the same disease It is for this reason that the introduction of a patient suffering from middle-ear disease into a scarlet fever ward may lead to a spread of middle ear disease throughout the ward though all the patients are infected already with a hæmolytic streptococcus but not perhaps with the particular type of this organism which had previously set up middle-ear disease in the newly arrived patient The same applies to other complications and it is clear that such swopping of streps is a very serious danger against which all possible precautions should be taken Such a precaution is the separate isolation of individual scarlet fever patients until at any rate the type of their infecting organism has been determined in the laboratory or can be assumed from the circumstances attending their infection (for instance two members of the same family or two children definitely infected one by the other or both from a common source) In the fever hospital this isolation can be effected either by barrier nursing (that is to say by treating individual patients in a many bedded ward as if they were in separate wards and suffering from different diseases) or by accommodating the patients each in a separate cubicle These precautions are being increasingly adopted in infectious diseases hospitals and have reduced the incidence of complications and consequently the frequency of permanent damage and the length of stay in hospital very considerably wherever they have been employed The view is gaining ground that the isolation period in cases of scarlet fever free from complications should be reduced (except in special cases) from the old six weeks to three weeks or less and where this has been tried complications have been fewer for the reasons which I have just given and much expense and waste of school time has been saved

VARYING PERIODS OF INFECTIVITY

Our views about the duration of infectivity in *various diseases have changed greatly in recent years* as the result of both bacteriological and epidemiological investigations Scarlet fever is an example of this change The significance with regard to infectivity of complications involving a discharge from the ear or nose in this disease as also in diphtheria has been recognised for a good many years now but the bogy of peeling *has been laid much more recently* and I am afraid not yet completely The skin that flakes off because of the preceding rash and when the patient is recovering from the disease is now known to be of very little importance as an infective agent so that it is now considered unnecessary to isolate the patient until this process is complete or *to make him sore by scrubbing or pulling off the* flakes which are not yet ready to separate Another disease in which the period of infectivity had previously been much over-estimated is whooping cough It is still popularly supposed that a patient suffering from this disease is infectious so long as they whoop whereas it has been clearly demonstrated that on the contrary by the time the whoop *first appears* the patient has already ceased to be infectious Much the same story might be told of measles which is most infectious in the early stages before the rash appears soon after which the child probably ceases to be a danger to others Influenza and the common cold are also probably most (or perhaps only) infectious in their early stages

THE SERIOUSNESS OF CERTAIN DISEASES

Anyone who can look back to the beginning of this century will be aware of great changes in the respect with which various infectious diseases have been regarded The most striking instance of this is perhaps small pox a very serious killing and disfiguring disease in the past that is now regarded by *many in this country as a trivial ailment tiresome* because of the isolation which it involves but not serious enough to make even the slight inconvenience of vaccination worth while I do not propose to enter now into the controversy which has raged and still rages around the question of compulsory vaccination and I would only remark that in spite of the undoubted change of type of the disease as seen in this country and the very thorough precautions taken at our ports to prevent the entry of major small pox from abroad I cannot forget the terrible cases of confluent and hæmorrhagic small pox *with which* I had to deal in Willesden in 102 or *the fact that the* first traceable case in this epidemic had no definite illness and only two small spots and I confess that I view with some alarm the rapidity with which the population of England is becoming unprotected by the neglect of vaccination

Scarlet fever is another *instance of a disease* which has become far milder in the last fifty y but judging from the history of epidemiology it would, I think, be unwise to assume that it will always remain so.

Measles and whooping cough deserve mention here for a different reason. These two diseases because they are usually of a trivial nature are unfortunately still often regarded as of little danger to the infected child and such ignorance is responsible in a large degree for the death of about 2000 to 3000 children from measles and 2000 children from whooping cough every year. These children are killed by the pneumonia which often supervenes in these diseases and leads to death. This danger has been pointed out by many concerned with the public health, but it cannot be too widely made known as these deaths are mostly preventable if the danger is realised and good conditions and nursing secured for the child before it is too late. Hospital accommodation cannot of course be provided for every case of measles or whooping cough, but in my opinion a good many of the isolation hospital beds now used for scarlet fever might, by reducing the isolation period for the latter disease, by the more economical use of beds made possible by the provision of more small wards and cubicles, and by isolating scarlet fever cases in their own homes wherever possible, be made available for those cases of measles and whooping cough in which home conditions, the debility of the child, &c., make the danger of pneumonia especially great.

Disinfection and Prevention

The word "disinfection" suggests, perhaps, first of all the treatment of rooms, furniture, clothing, &c. that have been used by a patient suffering from an infectious disease so as to remove all danger of other people becoming infected. Disinfection to be effective, however, may obviously need to be directed also to the destruction of disease germs on the body or in the nose, throat, gall bladder, &c. of the patient or of a carrier who caused his infection or who was infected by him. The best example of the persistence of an old practice long after the conclusions upon which it was based have been shown to be false is again scarlet fever. Consider what happens when a case of frank scarlet fever with all the classical symptoms occurs in a family. On the grounds that this is the first case of the disease in this particular household, that the infection has therefore been contracted outside, and that if promptly removed the infection of the other members of the family may be prevented, the patient is removed to an isolation hospital. Now we know, as I have already remarked, that scarlet fever is only one of the many different manifestations of infection by a hæmolytic streptococcus, so that the patient in question may very well have been infected by another member of his family who is either suffering from tonsillitis, sore throat, or rheumatic fever, or who is merely a carrier. By removing the patient in such circumstances whilst leaving the original source of infection in the house one clearly does nothing to arrest the spread of the disease, which was once regarded as the primary object of the isolation of infectious diseases, but one which it seldom achieves, whilst one may leave behind cases requiring the treatment that is more and more coming to be regarded as the most useful function of the isolation hospital. The logical course would be to examine all the members of the household and to isolate any who are shown to need treatment and this is not infrequently done. Sometimes difficulties arise owing to the natural hesitation of doctors to diagnose a typical case as scarlet fever (usually the only way to secure their proper isolation) when this diagnosis may be rejected (from one aspect quite justifiably) by the medical officer of health or the medical superintendent of the isolation hospital. I am glad to say, however, that some of the more progressive medical officers of health in this country, with the approval of the Ministry of Health, have found ways of overcoming this difficulty, but the old practice still persists in places.

In large centres of population the ad hoc isolation hospital is probably the most practical and economical way of dealing with infectious disease as the beds in such a hospital can always be used fully or almost fully, and the equipment and staff can be efficient and sufficient. But in rural areas often the only solution found has been to make use of modern transport, reduce the number of hospitals, and concentrate the patients in a few good sized ones. Another and very interesting solution is, however, widely employed in Denmark, Sweden, and other northern countries, and I mention it as a practical demonstration of the value of a realistic attitude in dealing with such problems. In these countries each county or other fairly large rural district is provided with a general hospital of perhaps 80 to 100 beds, with an administrative, surgical, medical, maternity, and—mark you—infectious disease block. The infectious disease block is usually an integral part of the group of blocks, and though of course not connected with the other blocks it is only separated from them by a short distance—perhaps twenty to thirty yards—yet spread of infection to the other parts of the hospital never occurs, thanks to a simple but efficient routine by which the nursing staff have their midday meal in the infections block and change their clothes and wash when they come off duty and before mixing with the other nurses. Such a plan has the advantages of providing for infectious patients within reasonable distance of their homes, economy in administration, and the availability of all the medical, surgical, radiological, and laboratory facilities, both of staff and apparatus, for diagnosis and treatment.

CURRENT AND TERMINAL DISINFECTION

To return to the subject of disinfection, a great deal of money, time, and trouble has been wasted in the past on applying general methods of disinfection to every kind of case instead of suiting the procedure to the particular circumstances. Disinfection to be rational should surely be founded on knowledge of the infecting micro-organism concerned. For instance, the ultramicroscopic virus which causes measles is a delicate organism easily destroyed by exposure to light and air, whilst the anthrax bacillus is a highly resistant organism. Moreover, the ultramicroscopic viruses are peculiar in their resistance towards chemical disinfectants, being extremely resistant to substances such as carbolic acid whilst being readily killed by permanganate of potash.

In the past reliance has been placed chiefly upon "terminal" disinfection (the treatment of the patient's room, clothes, &c., after recovery or removal to hospital), whilst "current" disinfection (the treatment of infective material in the sick-room during the patient's presence there) has been much neglected. Current disinfection has however been shown in recent years to be all that is required in such diseases as measles, whooping cough, german measles, and diphtheria, terminal disinfection in such cases being confined to the free use of soap and water and thorough ventilation. A recent survey of the practice in regard to disinfection of a large number of countries represented at the Office International d'Hygiène publique in Paris (1934) showed that in the United States and in certain European countries terminal disinfection has been abandoned without any apparent increase in the incidence of infectious diseases. It is disappointing, however, to note that although this changed practice has been adopted in a number of large towns in this country we are apparently far behind the United States and certain other countries in this respect. The effectiveness of current disinfection depends, it is true, upon the thoroughness and intelligence with which it is applied, and is inapplicable in hygienically backward countries, but we should hardly care for our country to be so classified.

A MUNICIPAL ACCIDENT SERVICE

CARDIFF'S PIONEER SCHEME

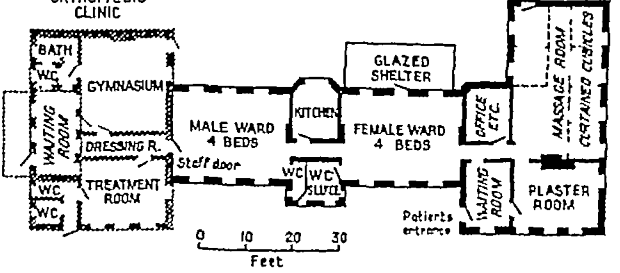
A JOINT *subcommittee including representatives of Cardiff city council and of the two voluntary hospitals*, viz., Cardiff Royal Infirmary and the Prince of Wales Hospital, was set up in January, 1936, to *consider matters of interest to the bodies concerned*. Recorded in the minutes of this subcommittee for April 20th, 1936, is a request from the representatives of the voluntary hospitals that the city council should undertake as much as possible of the work for accidents' and the representatives of the council willingly promised to do so. Thus did the voluntary hospitals of Cardiff give their blessing to a scheme, unique of its kind in this country, whereby the care of accidents is undertaken by the municipal authority with the coöperation of all the hospitals in the town.

The scheme as drawn up by the medical officer of health, Dr. J. Greenwood Wilson, has now been in operation for over a year, and the report on its organisation and first year's working has been submitted by him to the Interdepartmental Committee on Fractures. The space required for housing the accident service was found in City Lodge Hospital, a poor-law institution in the centre of the town, the medical service of which had been largely superseded by a new public health hospital at Llandough. The accommodation adapted to the uses of the accident service is shown in the accompanying plan. It was considered convenient to house the municipal orthopædic clinic in the same block, partly because the visiting surgeon is in charge of the clinical work both in the accident and in the orthopædic departments, and partly because there was a considerable amount of plaster work connected with the orthopædic treatment that could most conveniently be done by the sister in charge of such work in the fracture unit. Reference to the plan will show that the block of rooms as adapted contains two wards, one male and one female, with four beds each. The fracture clinic occupies the rooms to the right of the wards and the orthopædic clinic the rooms to the left. A portable X ray apparatus is a feature of the fracture unit; the films are taken, developed, and interpreted in the unit. Where necessary the help of the visiting radiologist and the use of the main hospital X ray plant are available.

City Lodge acts as a casualty clearing station with Llandough Hospital as the base hospital. Accident cases of all kinds are brought straight to City Lodge, where they are classified as (1) head injuries, (2) laceration of the soft parts, (3) fractures. First-aid treatment is given, X ray examinations carried out, and fractures reduced and splinted. As far as possible cases are sent home in their splints and appointments made for them to attend for out-patient treatment. All cases definitely needing hospital treatment are transferred, either immediately or after a stay of twenty-four to forty-eight hours, to Llandough Hospital. The eight beds in the unit are available for cases of head injury or shock not fit for immediate transfer, and also for patients recovering from anæsthetics, or with plasters which require time for drying. No open operations on fractures are done at the clinic. A minimum of 10 beds are reserved at Llandough Hospital for the visiting surgeon, and to these he can admit fracture cases requiring major operations.

The personnel of the accident service is a team consisting of the visiting (orthopædic) surgeon, Mr. A. O. Parker, a resident assistant surgeon, who is a member of the resident staff of City Lodge Hospital and has been engaged on account of his special knowledge of fractures, and a sister in charge of the plaster work. The two last named accompany the visiting surgeon when he goes to Llandough Hospital to operate on fracture cases. They also independently visit Llandough to supervise the treatment of patients transferred there, to adjust extensions and follow up results, and so forth. The clerical work is done by a clerk typist who keeps records of the cases, entering particulars on the record cards and typing the clinical notes from dictation. She also types correspondence with general practitioners, files and indexes records and X ray films, and interchanges notes between the unit and Llandough Hospital. An almoner recovers

FRACTURE UNIT



a proportion of the outlay from insurance companies under the Road Traffic Act and from other sources. From March, 1936, when she was appointed, to the end of July, 1936, a sum of £789 was recovered. The total cost from September, 1935, to July, 1936, was £2492. It is anticipated that with increasing experience more and more of the cost will be recovered. There is a scale of charges of which some of the items are: initial attendance (for private patients), five shillings; massage, per visit, eightpence to one shilling; plasters, three shillings to six shillings; dressings, sixpence; residential treatment per day, 4*s.* 3*d.* at City Lodge, 11*s.* 7*d.* at Llandough Hospital.

Dr. Wilson regards the Cardiff fracture service as an example of what can be done with existing resources without embarking on new and costly schemes of building and equipment. The adaptation of the whole block at City Lodge Hospital cost £290, of the fracture clinic itself, £161. The clinic was equipped with all essential apparatus, including a Hawley table, a portable X ray plant, filing cabinets, and radiant heat baths, for the sum of £370 10*s.* The number of new cases treated at present is well over 100 a month. Since its opening in September, 1935, 973 cases have been treated (with 2917 attendances), 508 as out-patients, the remainder being admitted to beds either at City Lodge or Llandough. The statistics submitted show a wide range in the type of fracture treated, and the results are encouraging. Patients with Colles's fracture for example, have returned to work at once, and the wrist has been normal, requiring neither splinting or treatment, in six weeks. Pott's fractures have been restored to normal in 12–14 weeks.

The routine work of the unit is done by the resident assistant surgeon. He sees daily all fractures that require it; twice a week he has under review all cases attending the clinic. The visiting surgeon attends twice weekly and has referred to him all complications of special difficulty. He is on call for emergency cases in which his advice is needed, and, of course, takes charge of cases admitted to Llandough.

The service is worthy of special note because it would appear to be the first attempt on the part of a municipal authority in this country to take responsibility for dealing with all the accidents in the area, and because of the coöperation which has been achieved between all the hospital services of the city. The low cost of equipment and the possibility of recovery of a substantial proportion of the running expenses may well encourage other local authorities to follow suit.

MEDICINE AND THE LAW

The Registered Pharmacist's Monopoly

AN Ilford firm of druggists was fined last week for unlawfully using the description "pharmacists" when not registered under the Pharmacy and Poisons Act of 1933. The solicitor to the Pharmaceutical Society (the body entrusted by Parliament with the registration) prosecuted under Section 3 of the Act. The defendant company, he said, had sold cough and neuralgia mixtures in bottles labelled "Hankinsons Cash Pharmacists." This was likely to mislead the public into believing that the retailers were qualified chemists. In 1929 the firm had been fined for applying a false description to goods and in 1930 for unlawfully selling poisons. The defendants said they thought they had a period of grace wherein to discontinue the use of the description and to change the labels. The bench pointed out that the firm had plenty of time in which to become acquainted with the Act of 1933, Section 3 of which was brought into force on May 1st last. A fine of £10 was imposed on each of two summonses.

Sections 1 and 2 of the 1933 Act, dealing with membership of the Pharmaceutical Society and the issue of certificates of registration, took effect at the end of 1933. The conversion of membership from an optional to a compulsory basis has naturally led to a large increase of members. While the Act in effect makes the society generally responsible for the training, registration, and supervision of pharmacists, Section 3 forbids unregistered persons to use the title of "chemist and druggist," "druggist," or "pharmacist," or, in connexion with the sale of goods by retail, the title of "chemist." It also forbids the use of any title, emblem, or description reasonably calculated to suggest the possession of qualifications which are not in fact possessed. One test case has already established that the use of a sign bearing the words "Chemists' Sundries" infringes the Act. This statutory restriction of the right to a professional description has special significance for the public because the sale of poisons is, by other parts of the 1933 Act, substantially restricted to registered pharmacists carrying on business in registered premises under the personal control of a qualified chemist. Parliament was not thinking so much of strengthening a professional monopoly as of protecting the community from serious risks which are inevitable if poisons are too easily obtained or if the retailer is ignorant of the properties of the goods he sells and subject to no supervision.

BUDAPEST

(FROM OUR OWN CORRESPONDENT)

THE EÖTVOS LORÁNT RADIUM INSTITUTE

A NEW institute for X ray and radium therapy named after the Hungarian physicist, Baron Lóránt Eötvös, which was recently opened, is said to be the largest in Central Europe. There is accommodation for 100 in-patients, and the equipment and apparatus are designed on the most modern lines. The radium department has bought 4742 mg. radium from a Brussels firm at 35 dollars per mg. The X ray therapeutic apparatus is on the Chaoul system, and plans are now being made for the construction of two further units, each of 400 000 volts. The director of the institute is Dr. William Manninger, professor of surgery in the University of Budapest.

CALORIC NYSTAGMUS

Who discovered that the nystagmus caused by a hot aural douche is due to the heat and not the pressure of the fluid? The discovery is commonly attributed to Bárány, professor in the University of Upsala and a winner of the Nobel prize, who was of Hungarian descent. Dr. K. Martin Sugár however takes up the cudgels on behalf of the late Prof. Andreas Högyes, and claims priority for him. He maintains that though Högyes in his experiments may not have applied heat and cold directly, he provoked nystagmus with various irritant and destructive agents, and alluded to the effect of temperature, showing that ice merely applied to the mastoid groove produced bilateral nystagmus. Even those who oppose Högyes's claim acknowledge that Baginsky had stated in 1881 that excessive temperature was responsible as well as the pressure in the tympanic cavity But it has been pointed out that Högyes then entered into a debate with Baginsky and denied the action of increased pressure saying that the sole factor was the irritation of the labyrinth by heat

THE ANTAGONISM OF THYROXINE AND VITAMIN C

J Mosonyi who has been giving thyroid hormone to guinea pigs, has found that the vitamin C content of their adrenals and liver is considerably decreased because these organs at once secrete a greater amount into the blood This may be concluded from the fact that after the administration of thyroxine more ascorbic acid than normal is excreted in the urine We can assume says Mosonyi, that it is the thyroid that physiologically regulates the appearance of vitamin C in the blood stream But after removing the thyroid the excretion of vitamin C in the urine does not decrease which shows that there are other factors besides thyroxine which act in the mobilisation of the vitamin C According to Mosonyi's test the testicular hormone proved to be most effective

EXPERIMENTAL IMMUNITY IN SYPHILIS

Dr J Vásárhelyi has treated 16 syphilitic rabbits with large doses of neoarsphenamine—3 doses of 0 10 g per kg of body weight, 110 247 and 333-409 days after the infection—and reinfected them after 85-90 days No clinical symptoms appeared in any animal. After further inoculations spirochætes could be found after 75-127 days only in 4 of the animals the remainder being entirely free from both symptoms and organisms On these grounds Vásárhelyi feels justified in stating that the drug produces immunity

SUICIDE STATISTICS IN BUDAPEST

The Ambulance Society has just published the 1935 suicide figures in the capital There were 2252 cases—924 men and 1328 women The commonest agents (1218 cases) were the poisons chiefly the narcotics veronal and morphine caustic soda and vitriol. Stabbing was responsible for 220 deaths and gas for 205 There were 167 suicides in the Danube most being women 148 hanged themselves 90 jumped from higher floors of buildings while firearms were used by 93 There were 33 who threw themselves before trams buses and trains

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

THE following promotions have been made —

Surg Comdr (D) to Acting Surg Capt (D): A Lawrey O.B.E

Surg Lt Comdr (D) to Surg Comdr (D): H J Luck, T Hunt and C J Finnigan.

Surg Lt -Comdr R. L G Proctor to be Surg Comdr

Surg Comdr (D) F R. P Williams to *Pembroke* for R.M Infirmary Deal

Surg Lt.-Comdrs. (D) R W Stevens to *Excellent* and J M Park to *Suffolk*.

Surg Lt S R G Pimm retires at own request

Surg Lts. P G Burgess to *Abingdon* G A Lawson to *Drake* for R.N Hospital, Plymouth; and M G Peever to *Endeavour* (on commg)

Surg Lt (D) D N Williams to *Malaya*.

H W Gibbs entered as Surg Lt (D) for short service and appointed to *Victory* for R.N Hospital, Haslar

ROYAL NAVAL VOLUNTEER RESERVE

Surg Capt L. S Ashcroft V.D has been appointed an Honorary Physician to the King from Jan. 1st 1937 in succession to Surg Capt J B Ronaldson V.D who then vacates his appointment

Surg Lt -Comdr W J Payne to be Surg Comdr

Surg Lt -Comdr (D) L A T McLean to *Victory* for R.N.B

ROYAL ARMY MEDICAL CORPS

Lt -Col and Bt Col (temp Col) R. C. Priest K.H P and Maj (temp Col) A G Harsant O B E relinquish the temp rank of Col on ceasing to be empld as Consulting Physician and Surgeon respectively to the Military Forces in Palestine and Egypt

Lt -Col C M Finny O B E to be Bt -Col

Maj S Smith to be Bt. Lt -Col

Lt -Col (temp Col) S W Kyle relinquishes the temp rank of Col. on ceasing to be empld as A D.M.S 5th Div

The undermentioned Lts (on prob) are confirmed in their rank :—

J F Wilson and A B Dempsey

The results are announced of the examination (in written subjects) of officers with a view to promotion The successful candidates were: Maj W R D Hamilton and Capts F McL. Richardson W R C Spicer H. A Ferguson, P J L. Capon, J L. Snow and A N T Meneces

Short Service Commissions: The undermentioned Lts (on prob) are confirmed in their rank: J A O Gorman R Walker D V Taylor D S Wilson and T A. Smitham

TERRITORIAL ARMY

Capt E Shipman, from Univ of Lond. Contgt (Med Unit) Sen Div O T C to be Capt

W N P Wakeley (late Offr Cadet R.S.M Univ of Lond. Contgt Sen Div O T C) to be Lt

J M Matheson (late Offr Cadet Serjt Edinburgh Univ Contgt (Med Unit) Sen. Div O T C) to be Lt

The undermentioned promotions are made :—

To be Bt Lt -Cols: Majs L McI Weeks M C T.D J Marshall M C and A Topping T.D

Lt T Gibson from T.A Res. of Off (23rd Lond R) to be Lt

ARMY DENTAL CORPS

Maj A T Madin is placed on the h p. list on account of ill health

ROYAL AIR FORCE

Group Capt B A Playne D S O to be Air Commodore

Wing Comdrs R. J Aherne M C. and T Montgomery to be Group Capts

Squadron Leaders J G Russell, J B Gregor R H Stanbridge R. W White G P O Connell and A Dickson to be Wing Comdrs —

Flight Lt A. H Osmond to R.A F Station Leconfield

Flying Offrs G I Jones to R.A.F Station Dishforth D F S Shaw to No 2 Flying Training School Digby G B Macgibbon to No 3 Flying Training School Grantham E J Moynahan to No 6 Flying Training School, Netheravon; J R Collars to No 8 Flying Training School Montrose; J D Cran to No 9 Flying Training School Thornaby and J H. Preston to No 11 Flying Training School Wittering

Flying Offrs L M Crooks C F R. Briggs and W J Fowler to be Flight Lts.

Dental Branch.—Flying Offrs R. M Brown and W I Nelson to be Flight Lts.

INDIAN MEDICAL SERVICE

Maj A H Craig to be Bt Lt -Col

Maj R. Sen to be Lt -Col

GLASGOW HOSPITALS —The sum of £15 001 the residue of the estate of Mr A M Hunter has been equally divided among the Royal, Western and Victoria Infirmaries and the Sick Children's Hospital while the residue of Mrs Hunter's estate £14 8[illegible] has been [illegible] among the three infirmaries

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations Each contributor is responsible for the section for a month, his name can be seen later in the half yearly index

FROM A PUBLIC HEALTH CLINICIAN

II

WITH *Physical Education* on the hoardings and *Physical Fitness* on the air it behoves us doctors to reflect thereupon, and maybe to comment thereanent Athletics and other exercises may help to create sound bodies and to prolong life, but to be a successful athlete implies the possession of a sound body, and its possessor is likely to live long if no accident waylays him a motor calamity for instance, cancer, or a serious infection It is arguable that such a one might have lived still longer had his arteries not been strained by exertion, but no figures are available, as far as my knowledge goes, to promote this argument from a conversational to a scientific plane

The importance of athletics and ball games is not confined to muscular growth, such pursuits also train the eye, quicken the reactions, and by improved coördination make skilled movements more possible The question has other aspects also, for the coöperation and spirit of ball games has a social value, discipline is promoted, self control developed, and a knowledge of human nature obtained The fortunate 20 per cent amongst us who are good at games, especially perhaps the fiercest of them, Rugby football, will probably grow wise and experienced at a younger age than the remaining 80 per cent The wisdom so gained will prove invaluable later in public work, be it in council, committee, or as a member of a local authority We see statues to various notable and great men in Trafalgar square and Westminster Abbey, statues elsewhere to the Black Prince or Queen Boadicea, but never to the world's greatest benefactor the inventor of the ball. Perhaps there was no one inventor, but even then, as an abstract conception, he still deserves commemoration

But the creation of general physical fitness is not so simple as might be inferred from much that has been written, it is not enough, alas, to talk about it or to prescribe exercise or diet Any exercise allowance must vary widely both individually and with regard to age Consider for a moment the factors conducive to longevity In order of merit I would put constitution, luck, avoidance of accidents in the broadest sense, and no excesses, yet the alcoholic who escapes damage to vital organs may survive to a ripe old age, an explanation of which may perhaps be found in the amount of water swallowed with the alcohol

Conversing with a much respected, elderly, but by no means senile colleague, he disclosed the rules of life which had been responsible, in his case, for a healthy and happy old age The first was "take no exercise," the second 'keep warm" A little reflection will suggest that there may be something in it Nevertheless there are advantages in keeping before the public the aim of physical fitness

* * *

Some of us sometimes wonder if it is always proper to advise patients so to order their lives that they may *live long* regardless of any entailed curtailment of their beneficient activities It is obviously advantageous to insurance companies that everyone should live as long as possible, but the benefit to the community is less obvious, it is much more obvious that everyone should persist as long as possible in activities which indirectly or directly assist the rest of us even though by so doing the individual may shorten his life This does not refer to euthanasia for the relief of suffering from incurable disease (that is another story), but to advice that may be given to a business man, or professor, that perhaps his blood pressure is rising, and that he should reduce his work by half Even so life may not, as it happens, be prolonged but according to the present tenets of our profession it ought to be Many maintain, rightly I think, that it is deeds and achievements that count and not longevity Those with high blood pressure are often among the very ones who achieve things

A colleague leading an active life confided to me that his blood pressure was very high—should he retire? He could ill afford it "Take no notice of it," I suggested, "and see what happens" That was 14 years ago, and he is still in active work. This experience led me to give similar advice more boldly to another colleague similarly handicapped, and with similar results Incidentally I suspect that some such blood pressure readings, as well as certain others followed by a rapid cure under treatment, are single readings taken when the patient was highly strung or mentally disturbed for some reason, and a reading repeated the following morning might have given a very different figure But it is true we all encounter cases where a high blood pressure has disastrous consequences

* * *

Psychology and dream interpretations are no longer such popular dinner time topics as they were 10 to 15 years ago My own knowledge of the subject is limited Some years ago feeling anxious to learn something of the progress in those directions I selected as the subject of a promised lecture "dreams and their interpretation," and it therefore became necessary to read books by Freud, Jung, and Adler A smattering of information was thus obtained, and I developed views, perhaps ill founded views, on the latest work It seemed that the authors cited had ploughed new ground and stimulated much useful thought, but some of the things written appeared perilously near to nonsense For instance, the suggestion that the not uncommon dream when the dreamer is attempting to crawl through a confined space is a prenatal recollection of his fœtal feelings experienced during the act of birth Perhaps the time has now come to leave our guides behind and think again In Russia, I am informed, Freud and his school are ignored, and thought and psychological research are proceeding along more novel lines

It may not be a retrograde step to seek dream explanations more frequently from physical sources. Surely the dreams to investigate are preferably the common dreams which are likely to have an equally common origin Dreams of flying and trying to escape when the feet cleave to the ground may be quoted and may well have a physical basis Once we solve these simple dreams we may secure factors which will enable us to split up and analyse more complex pictures Such common dreams as anxiety about passing an examination which in reality we passed 30 to 40 years ago or of forgetting an appointment or of leaving things behind may likewise have a simple, though in their case a psychical, basis

The flying dreams seem to me to have their cause in a partial awareness of respiration The flight is usually up and down and not in the same horizontal plane Again it is difficult sometimes to move a limb when just beginning to be aroused from sleep and that might be the basis of the dream with cloying feet A friend tells me that whenever he goes to sleep with a feeling of nausea he is likely to dream of being on a ship at sea or to see waves passing rhythmically before his eyes. For this the explanation seems simple though not romantic

But enough of these reflections or the writer will be out of his rather shallow depth.

* * *

A South African experience compelled me to share a room with a bricklayer and a more perfect bedroom companion I have never met There was no egotistic scramble for the minor comforts of life but the self sacrifice and courtesy of a Spanish Grandee which soon became mutual Pondering why this man whose education had been elementary was such a pleasant companion while others we encounter who may have been to Eton and Cambridge are not always so pleasant, the answer seemed to be that this one had been trained in the best school of all—*adversity*—an advantage not shared by everyone Shakespeare and others have told us of the uses of adversity and most doctors could tell how they have seen characters tempered and improved by adversity and suffering Not all natures will react favourably to difficulties but fortunately the great majority do so react

* * *

The value of *quotation* in speech and writing has much diminished The Victorians enriched their heavy orations with long Latin or Greek quotations which would bore hearers to day and indeed did little more even then than advertise the classical erudition of the speaker To day many speakers still interpolate poetry or prose quotations suggesting again the erudition of the speaker but often without clarifying the subject under consideration. In the past I have made another use of quotation; if a trite aphorism or bright idea came to my mind I would produce it as a quotation from some distant author It seemed that an audience paid more attention to my ideas if attributed to Dante or Milton of whose pages I am in fact profoundly ignorant To-day with the passage of years I rarely use quotations but endeavour to express myself clearly and give no one else credit for my ideas If such a step belittles my learning it were just as well belittled. Such ideas have no doubt occurred to others in the distant past but there is no harm in restating them to-day

CORRESPONDENCE

HÆMORRHAGE IN GASTRIC AND DUODENAL ULCER

To the Editor of THE LANCET

SIR,—In your last issue Hurst and Ryle state that the danger of hæmorrhage from peptic ulcers has been grossly exaggerated in papers recently appearing in British journals. I cannot help feeling that this statement calls for examination. Hurst, from figures collected by Baboy[1] says that the mortality rate for cases of peptic ulcer admitted under his care to Guy's Hospital on account of recent hæmorrhage and in which death was directly attributable to hæmorrhage is 4 8 per cent Compared with this Baboy sets out a table showing mortality rates of hæmorrhage from ulcer given by various authors some of which are over 20 per cent This table is misleading because no mention is made of the different criteria adopted by the various authors when compiling their statistics. For example Conybeare[2] arguing from the number of post mortems of all cases admitted to Guy's Hospital for hæmatemesis or melæna from 1911 to 1920 (inclusive) showed a mortality of about 4 3 per cent Burger and Hartfall[3] found the mortality from severe hæmatemesis at the same hospital from 1921 to 1930 (inclusive) to be 22 6 per cent. The last figure includes deaths from complications and there seems no useful reason why they should be omitted whether from cardiac failure or even following surgical intervention It seems quite clear therefore from a study of the available statistics that omitting cases of melæna the death rate in hospitals from severe hæmatemesis has not been exaggerated and is still disturbingly high. Another evident fact not stressed by Hurst and Ryle is that repeated hæmorrhage is the most serious prognostic sign A single bleeding however severe is rarely fatal. The mortality in Hurst's cases at Guy's which had further gross bleeding in the wards was 27 per cent.

With regard to blood transfusion another important point dealt with by these authors we found when examining a series of cases (Cullinan and Price[4]) and by subsequent experience that when it is considered necessary to transfuse because of severe anæmia it is wise to wait until several hours after the gross bleeding has ceased Not only does transfusion of itself fail to arrest hæmorrhage but it may even cause further bleeding if performed immediately To this rule there is one exception: in cases with severe anæmia when gradual bleeding has been going on for several days transfusion may be a life saving measure We also thought that the giving of enemata before the sixth day after a severe hæmatemesis carried a risk of further bleeding

I do not wish to imply in any way that because the mortality in hospitals from severe hæmatemesis is high that this is any reason for more frequent surgical intervention For the reasons Hurst and Ryle so clearly state immediate operation is very seldom desirable Their plea for the avoidance whenever possible of disturbing therapeutics and for treatment with quiet and rest in the widest sense is unassailable Courage lies not in action but in confident inaction

I am Sir yours faithfully

EDWARD R CULLINAN

Park Square West London Jan 4th

IN MEMORY OF JOHN BLAND-SUTTON

To the Editor of THE LANCET

SIR,—Perhaps a few lines may still be spared to one who was an old assistant surgeon of Sir John Bland Sutton at Middlesex Hospital, and who chances to be in surgical charge of the ward in the hospital which bears the name of the distinguished surgeon whose death we deplore

From former colleagues and from other distinguished surgeons who had come under his spell appreciative notices have already appeared in your columns, penned in words far more eloquent than mine , but none I think has done quite full justice to the really extraordinary dexterity, the craftsmanship, and the operative celerity of the man more especially in the surgery of the female pelvis, the branch of surgery which, as has already been pointed out by others, he did much to found and which he advanced and adorned

For many years I rarely missed his Saturday operating afternoon at "Middlesex" , he came at 2 o'clock and left precisely at 4 o'clock, having completed his regular quota of four "cœliotomies" for conditions as varied as a pathological spleen, a hydatid cyst, a cervical fibroid, or a cancerous colon He would have been the first to insist how much the afternoon's work had been expedited by the coöperation of his anæsthetists, formerly the late H Percy Noble and in the last fifteen years of his time at "Middlesex" by his loyal and devoted friend, Raymond Apperly None of his old house surgeons, dressers, or the spectators will ever forget his resource, his tricks of technique by which he facilitated the delivery and removal of formidable pelvic tumours, his sang froid and self reliance in unexpected crises, his urbanity and his unfailing courtesy whatever the emergency that might well have alarmed

If celerity at times led to error, none could have been more rapid to detect mistake or more speedy to make a quick decision and to rectify It required courage to open a bleeding extra uterine pregnancy without anæsthesia in a bed in a private house, to withdraw the gravid tube and to clamp it, while preparations were then made to deal more deliberately with the condition, and his success in removing the spleen in severe cases of pernicious anæmia long before the days of blood transfusion and of our present knowledge of medical therapy for this disease made his colleague, Dr Essex Wynter, regard surgery as the appropriate treatment for this malady

Although his warmest admirers cannot be blind to his technical imperfections in the surgery of the upper abdomen, when judged by modern standards, it must nevertheless be remembered that he was the second British surgeon to perform a successful choledochotomy, and nearly a quarter of a century ago he was practising gastro duodenal resection for non obstructive duodenal ulcer

Neither the "cranial box" nor the "thoracic cage" attracted him, although he did develop an interest in the surgery of the heart , his interests were centred in the "abdominal valise" and he was at his very best in its lower region

His pronunciation of some words was curious and the mention of this foible may still bring a smile to the lips of many, but if his rendering of the term "capsule" had no etymological support, his pronunciation of the word 'ureter' was backed by a Greek origin of which he was doubtless far more aware than those who were disposed to laugh pityingly at his supposed ignorance

His genius for friendship and for hospitality have been already referred to but his kindliness and generosity to the very junior may perhaps not be so well known, for in many instances his right hand knew not what his left hand was doing

I am, Sir, yours faithfully,

Harley street W Jan 4th GORDON GORDON TAYLOR.

AMALGAMATION OF HOSPITALS

To the Editor of THE LANCET

SIR,—On p 1550 of your issue of Dec 26th you say that it is proposed to "coördinate the work of" the Bristol hospitals (the local word is "amalgamate") so that each shall specialise in the type of case with which it principally deals—i e , surgery at the Royal Infirmary and medicine at the General Hospital. Another scheme proposes to collect all the "dont wants" (gynæcology, nose and throat, skins, &c) at what is now the General Hospital , but no details have been settled, and they are in any case immaterial Contrary to the implication in your note, each of these two institutions has for many years been a large teaching general hospital, completely equipped to treat every type of case—a state of affairs that it is proposed to end ! Were they adjacent, such a rearrangement of work might amount to no more than establishing a single unit in place of two But the Royal Infirmary lies outside the ancient city of Bristol, across the Froom river to the north west , the General Hospital lies just outside the ancient transpontine quarter of Redcliffe, south-east of the old city Between them lie a mile and a half of the narrowest and most crowded streets in the city, with the bottle neck of Bristol Bridge (with the adjacent wharves) in the middle Although 'bus and tram routes cross the city in most directions, no one has yet been daft enough to propose a route between these points It is from convenience rather than tradition that those living north of the Avon (even well outside the city) generally attend the infirmary, those living south the hospital. There is, in fact, no greater reason to "amalgamate" the two than to treat in the same manner, say, St Thomas's and the Westminster If it is desired to concentrate the really rare cases (so that, for example, one surgeon shall deal with all thoracic surgery another with all cerebral tumours) nothing more is needed than general agreement among the surgeons concerned—without which no "amalgamation" will bring concord There are many advantages in having more than one hospital , among others, the occasional disgruntled patient has at least the option now of trying his luck at another institution It is impossible to see what professional or economic advantages the scheme offers to public, profession, or science —I am, Sir, yours faithfully,

Dec. 28th 1936 BRISTOLIAN

ON WRITING FOR "THE LANCET"

To the Editor of THE LANCET

SIR,—I have been much interested in your supplement of this week (It might be counted as tautology to quote the title) If a humble reader, and occasional writer (this comes under the paragraph "Modesty") may be allowed to criticise, I think it is excellent in idea, but perhaps unduly severe on the use of certain words In my "opinion" theory is a most excellent word and difficult to replace However, that is only my "idea" A more serious criticism is your suggestion of the use of the word "disease" instead of "pathology," which is by no means a synonym The word pathology means the science of the causation of any given disease as illustrated by all the facts of morbid anatomy treatment &c

Your list of abbreviations for the titles of papers I am sure will be very useful, and I shall keep it carefully by me but what has the *Archives of Neurology and Psychiatry* (Chicago) done to be excluded ? Is its mere youth (18 years) the only reason ?

I am Sir yours faithfully

Wimpole-street W Jan 1st. WILFRED HARRIS

*** We agree with Dr Harris that the words are excellent in their place but some of them are certainly overworked and some as certainly misused '—— put forward the theory that the spleen was diseased is a bad way of describing his opinions and Dr Harris will share our horror at ——s discovery that the spleen showed no pathology The alternatives suggested are by no means always synonyms, but they will sometimes be preferable Our omission of the *Archives* from the list was accidental but at best the selection is a small one chiefly intended to illustrate the various kinds of abbreviation used —ED L

OBITUARY

SIR GRAFTON ELLIOT SMITH M D Sydney, F R C P Lond F R S

WE regret to record the death of the distinguished anthropologist Sir Grafton Elliot Smith which occurred on Jan 1st at Broadstairs For a long period he had been in delicate health

Grafton Elliot Smith was born at Grafton New South Wales in 1871 son of the head master of a large State school in Sydney He was educated there and at the University of Sydney which he entered at the age of 17 as a student of medicine As a schoolboy his high qualities were recognised and he came at once under the notice of Prof J T Wilson then professor of anatomy at Sydney who chose him as a prosector in the anatomy classes where he displayed his proficiency in the technique of dissection He won the John Harris scholarship and graduated as M.D with honours in 1895 The University of Sydney at that period was fortunate in the personnel of its staff and contact with such teachers as Almroth Wright and C J Martin accounted for much in Elliot Smith s early scientific development Aided by a travelling scholarship he came to England in 1896 and through the influence of Donald MacAlister was admitted as a member of St John s College Cambridge

SIR GRAFTON ELLIOT SMITH

[Photograph by Elliott & Fry

He was again fortunate in his association with co workers for at Cambridge Hugh Anderson J N Langley and Gaskell were eminently fitted to advise and encourage him During three strenuous years Elliot Smith s output of work included valuable researches on the comparative anatomy and morphology of the brain In recognition of these he was elected a fellow of St John s and in 1900 was invited to become the first occupant of the chair of anatomy in the Government medical school at Cairo In his new sphere while pursuing his anatomical work he became almost perforce an anthropologist For during his nine years stay in Egypt he conducted graveside investigations with archæologists who working with the best scientific methods provided him with an accurate dating of all the material that he handled He was appointed to supervise the anthropological survey of Nubia and examined a vast series of bodies representative of all periods of Egyptian history He was able to ascertain with astonishing detail the life history of the inhabitants of the Nile Valley 6000 years and more ago while he described the royal mummies for the general catalogue of the Cairo Museum In 1907 he was elected F R S and in 1909 was appointed professor of anatomy at the University of Manchester

From Manchester while continuing researches into cerebral physiology he published the outcome of certain of his anthropological work In 1915 there appeared a short work on mummification in which he formed from the geographical distribution of the practice his interesting theories on the migration of peoples and the spread of customs and beliefs He had followed up in his labours the evolution of tomb-building which culminated in the pyramids and he now traced the influence of Asia in the megalithic monuments of other parts of the world The result was the conclusion that the principles of architecture had been handed on to nation after nation by human missionaries a conclusion which involved him in an interesting dispute with American archæologists as set out in Elephants and Ethnologists a quarto volume excellently illustrated and published in 19?4 Here Elliot Smith deals with certain decorative sculpture found in Honduras whose artistic origin would seem to have been Asiatic for elephants played a large part in the ornamentation and there are no records of elephants in America But among certain learned men in America there was reluctance to believe that the early civilisation in their country had derived anything from Asia and Elliot Smith s book records an amusing interchange of personal views honours remaining with Elliot Smith For it is more probable that adventurous voyagers pushing east from Asia should have carried with them little specimens of household gods in which the elephant figured than that prehistoric Americans should have invented for the ornamentation of their early architecture an animal of whose existence they could not have known

Elliot Smith was for ten years professor of anatomy at Manchester We have received from Prof J [illegible] Stopford F R.S vice-chancellor of the University the following estimate which explains the great position which his late colleague enjoyed alike as worker and teacher

The passing of Sir Grafton Elliot Smith [illegible] from our midst a man of quite outstanding [illegible] who has made history in the fields of [illegible] and anthropology It was my good fortune to come under his influence at the outset of my career [illegible] and for seven happy years he was my [illegible] How well I remember my feeling of hopelessness and utter bewilderment when I first observed his inimitable methods of doing original work For days, sometimes weeks, he would delay making a start and appear to dip almost aimlessly into the literature and, as we described it, 'potter about' Then one day material from all parts of the department would be brought, quick dissections made, a few histological sections prepared, and within an incredibly short time the solution of the problem would be clearly exposed and explained. In spite of the long latent period at the start we all agreed that when once he got to work Elliot Smith could do more in three days than most of us could do in three months He was equally rapid when preparing his results for publication, and his style and method of presentation were an example never to be forgotten

"He attracted many research workers from other schools at home and abroad, and great was the disappointment of those who imagined that he would do the work for them Having suggested a line of investigation he appeared to take no further interest until some results had been obtained, but then his generous praise and encouragement were often out of proportion to the work accomplished Quick to grasp the meaning and significance of an observation, the master frequently advanced an interpretation which would never have been appreciated by the worker himself. His power to recognise at once the significance of a fact was unique and in my experience unequalled When the papers came to be written Elliot Smith never expressed criticism of the draft, but would take it home to 'polish it up' This process consisted of almost rewriting the text, and the original author might not be able to recognise his paper, but he would have no difficulty in appreciating what the unexpressed view of the original draft must have been

"Elliot Smith probably did more than any other person to reform the teaching of anatomy, and the younger anatomists are immeasurably indebted to him for his leadership and inspiration More clearly than anyone he saw the need for drastic changes, which were long overdue, and it is fortunate for British anatomy that he was provided with the opportunity of carrying them through in the institute which he planned and directed so successfully at University College In years to come it may well be that his influence upon the teaching of anatomy will be regarded as great and as valuable a contribution as his researches in neurology and the origin of man, which are so well known No one can replace such an outstanding figure, but the men he has trained can keep alive and foster the spirit which he created, and it is much to be hoped that this may be the way we should provide a permanent memorial to one to whom we owe so much"

In 1919, as indicated above, Prof Elliot Smith was appointed to the chair of anatomy at University College, London, in succession to Sir George Thane, and continued to display the fine qualities for the post already indicated During his tenure of the chair at University College it became possible, through support from the Rockefeller Foundation, to plan and build a new institute of anatomy where research workers came in large numbers to work, and as a result the professor's influence as trainer and teacher became pre eminent, and at various times he was invited to lecture in most of the principal centres of learning in Europe and America In 1919 he delivered the Croonian lecture at the Royal College of Physicians of London on the significance of the cerebral cortex from which his contributions to our understanding of cranial characters could be gathered. While he was at University College the discovery of the "London" skull occurred, when the examination and description of the relic was undertaken by him The problem of assessing the racial affinities of the skull was rendered particularly difficult because only its hinder two thirds were preserved, but from the part remaining Elliot Smith was able to demonstrate a strange mixture of characters, finding the bone of a London woman approaching those of the Neanderthal type He held the likeness to be so real as to raise considerations which were dealt with in detail by Sir Arthur Keith in "New Discoveries Relating to the Antiquity of Man" This work is mentioned as one example of the learned contributions to anthropology which came regularly from him, to enumerate these in detail is not possible here, and reference must be made to his books

Honours came rightly to him He was a medallist of the Royal Society, and received honorary degrees from many universities, he was a prizeman of the Anthropological Society of Paris, and an honorary member of anthropological societies in France, Germany, and Italy He was knighted in 1934.

Sir Grafton Elliot Smith married in 1900 Katherine Macredie, by whom he had three sons

ROBERT FRASER CALDER LEITH, M Sc Birm., F R C P Edin

THE death occurred at an advanced age on Dec 14th of the well known bacteriologist, Dr Robert F C. Leith, late professor of pathology and bacteriology in the University of Birmingham Second son of Mr R C Leith, he received his general and scientific education at the University of Edinburgh. Here he graduated in arts with honours, and commenced studying for the Scottish Bar, but determining to enter the medical profession, he graduated as M B, C.M. in 1885 with first class honours After serving resident appointments he was for a time tutor in clinical medicine at the Royal Infirmary, Edinburgh, and in 1892 was appointed pathologist to the institution, a post which he held for five years, being at the same time lecturer in pathology at the school of medicine of the Royal Edinburgh Colleges He made his mark as lecturer and teacher, and confirmed it by numerous papers in medical and scientific journals. He contributed largely to the third edition of Quain's "Dictionary of Medicine," and to the revised edition of the "Encyclopædia Medica," and wrote one of the articles on the stomach in Allbutt and Rolleston's "System" in collaboration with Lauder Brunton. His services were in unusually frequent demand as an examiner, for he discharged this duty at different times at the Royal Colleges of Edinburgh and Glasgow and at the universities of Cambridge, Bristol, and Sheffield In 1899 he was appointed professor of pathology and bacteriology at Birmingham, being at the time assistant physician at the Royal Infirmary, Edinburgh He filled the chair at Birmingham for over twenty years, and was successful alike as teacher and colleague For the past fifteen years he lived in retirement

GEORGE HENRY BURFORD, M D Aberd

Dr Burford, who died on Sunday last at his house in Queen Anne street after a brief illness, was in his eighty first year He graduated in medicine at Aberdeen in 1881, after taking prizes in most subjects and then held resident appointments at the Hospital for Women in Soho square, where he observed a mild form of septic toxæmia occurring after enemata which he reported in our own columns A little later he published valuable observations on the pulse as an indication for exploratory laparotomy in cases of acute traumatic peritonitis Having decided to specialise in gynæcology he became gynæcological physician to the London Homœopathic Hospital and was deeply attached to the homœopathic outlook on medicine He was president of the British Homœopathic Society in 1901 and later founded the International Homœopathic League Last year he was presented by Sir George Truscott on behalf of his colleagues with a testimonial to mark fifty years of active association with homœopathy

HARRINGTON SAINSBURY, O B E
M D F.R C P Lond

Dr Harrington Sainsbury who died on Dec 29th in London in sequence to an operation was a well known consulting physician and worker in cardiology He was born in 1853 received his early education mainly on the Continent and joined the medical school at University College Hospital in 1875 He graduated as M.B with *honours in* forensic medicine at the University of London in 1879 and proceeded in the following year to the M D degree He acted for a time as house physician at Pendlebury Manchester and as clinical assistant at the Great Ormond street Children s Hospital and was then appointed to the staff of the Royal Free Hospital. In hospital and private practice he devoted himself particularly to cardiac diseases and to the constitutional action of many pharmaceutical remedies His pharmaceutical work started as far back as 1882 when he wrote in connexion with Sidney Ringer on the action of salts of potash soda and ammonia on the ventricle of the frog while later he contributed to Ringer s well known Handbook of Therapeutics He was for a time physician to the City of London Hospital for Diseases of the Chest Victoria Park and acted also as examining physician to Ventnor Hospital for Consumption He wrote considerably papers from him being published at different times in the *British Medical Journal The Lancet Folia Therapeutica* and the *Transactions* of the Medical and Chirurgical Society But Sainsbury revealed himself more completely in two small text books. Drugs and the Drug Habit " published in 1906 set out in popular language the theories underlying medical treatment by drugs and was addressed rather to a lay public Principia Therapeutica three years later was addressed to the clinicians who even then were in peril of being engulfed in the flood of new remedies ' In scholarly words he breathed life into the materia medica, accompanied the pathologist into the dead house to discuss them and enjoined respect for the many and various ' imponderabilia Some fifteen years ago there came from him a discussion of certain problems concerning the normal circulatory mechanism which displayed him as an able anatomist while several works of a popular and romantic character were due to his pen

DR. SAINSBURY

[Photograph by Elliott & Fry

We have received the following tribute from Dr J W Carr —

Sainsbury and I were colleagues for 20 years at the Royal Free Hospital and the better I got to know him the more I learned to respect and esteem him, for he was essentially a man who wanted knowing intimately He was so quiet and shy so retiring and self-effacing that it was only on close acquaintance that one realised his true worth. As a physician he was sound and thorough sparing no pains to reach a correct diagnosis and to do the utmost possible for his patients. In that great testing chamber the post mortem room his diagnoses were usually proved to be not only accurate but thoroughly well worked out

So quiet and reserved was he that only by experience did one learn that his convictions based on careful observation and deduction were held tenaciously and firmly Religion to him was a very real thing and as his personal character was of the highest it was impossible to conceive of his doing or saying anything underhand or mean Everything he undertook was carried out absolutely conscientiously to the smallest detail This characteristic was reflected in his writings for he wrote most polished English so that his meaning was always clear and perfectly expressed Naturally he was trusted and beloved by his patients whilst to his students he was always the courteous gentleman most ready to answer any questions they might put to him The world is the poorer for his passing for men of his type—quiet, unselfish, unassertive unpushful, but thorough, accurate painstaking and meticulously scrupulous in every detail of daily life are indeed rare and often not sufficiently appreciated in a world in which self-assertion is only too frequently taken at its face value

ROBERT WILLIAMS M.B Edin

THE death occurred on Dec 27th of Dr Robert Williams who had a lifelong association with the town of Leominster and the district He was 87 years of age and died at Kingsland where he was born as were two generations of his ancestors He was educated at the Hereford Cathedral School, and having graduated in medicine at the University of Edinburgh in 1874 took up the family practice at Leominster and was for 50 years medical officer of health for the borough only ceasing to practise some ten years ago We owe to one of his oldest friends the following note : Dr Williams was essentially a countryman He had lived in his native village of Kingsland since his school days and during all his long life he identified himself with the life of the neighbourhood Foremost in promoting anything that might be of material benefit to his neighbours especially the children he helped to raise funds for many worthy objects in the village by a long series of amateur play productions extending over 20 years He was particularly keen on the natural history of Herefordshire and had an unusual knowledge of birds and their habits. His collection of birds' eggs was valued at several hundred pounds His many friends in Herefordshire and elsewhere will miss genial 'Dr Bob', especially will he be missed in the charming village of Kingsland"

GEORGE McWILLIAMS HENRY, M R C S Eng

The death occurred on Christmas Day in his 80th year of Dr George McWilliams Henry, who was for many years in practice at Halifax He was born in Co Tyrone, and was educated at the Heath Grammar School and University College, London On qualification he went to Halifax, where he had previously resided as a boy with an uncle, and during the next quarter of a century became one of the best known medical men in the district Dr McWilliams Henry, surgeon to the Halifax Infirmary, is his son, and father and son were in partnership until the retirement of the senior member of the firm in 1923 Dr George McWilliams Henry married a daughter of the late Mr John Crossley of Hopwood Hall, Halifax, and celebrated his golden wedding in 1932 After retirement from practice he went to live at St Anne's-on Sea, where he died

JOHN WILKINSON, M D Edin, D P H

Dr John Wilkinson, who died on Dec 17th at his house in Droitwich, was the senior medical man in the borough, where he had been M O H for over thirty years Born in Dublin in 1863, he was educated at Birkenhead, and received his medical training at King's College Hospital, London. He graduated at Edinburgh in 1886 and was demonstrator of bacteriology in the medical school at King's Later he was for a time resident medical officer at an institution in Bath, but in 1900 he joined the late Dr P A Roden in practice at Droitwich, remaining later in partnership with Dr K S Roden until he retired in 1935 Dr Wilkinson was a sound practitioner and popular with his patients, into whose general troubles he seemed particularly able to enter while giving medical counsel. He was twice married, and leaves a widow and a daughter, the child of his first wife

PANEL AND CONTRACT PRACTICE

The Insurance Medical Service

In the annual report of the chief medical officer of the Ministry of Health, insurance practitioners will be particularly interested in the five pages headed "The Insurance Medical Service" Sir Arthur MacNalty points out that not only the insured persons and their employers but the State also is closely concerned in preventing avoidable disability by the early diagnosis and treatment of incapacitating disease among the workpeople, because from the point of view of preventive medicine the free access of close upon sixteen million insured persons to medical advice provides the best opportunity for the early detection and notification of those infectious conditions that are a direct menace to the nation's health The insurance medical service rightly, therefore, takes its place as one of the most effective branches of the public health service The smoothness of working of this vast scheme may be regarded as generally recognised On a conservative estimate in each year eight million insured persons seek medical advice and over fifty million attendances are given by doctors In these circumstances it is remarkable that during 1935 it was found necessary to investigate only 157 complaints, no more than 48 of which justified the imposition of a penalty This is negative evidence, but from competent observers there is also ample positive testimony to the success of the service

Sir Arthur remarks that the vast majority of insurance practitioners interpret the terms of their contract in no niggardly spirit and, undoubtedly, the standard of the service they give is yearly rising with fresh advances in diagnosis and treatment He comments on the steadily growing interest shown by practitioners in post graduate courses and expresses the opinion that perhaps nothing else is so important in the maintenance of a high standard of clinical work

Cost of Prescribing

The returns for 1935 show that the already very high expenditure of prescribing for insured persons has risen in the year by 1*d* per head of the insured population in England and by 1½*d* in Wales representing an increase of about £70,000 Analysis of the returns shows that, while part of this was due to the prescribing of the more costly modern preparations much the larger proportion was due to the issue of a greater number of prescriptions There are no known facts about the incidence of disease in the country that would account for this substantial increase in the amount of medicine consumed by the insured population

The sum of 35*d* per head is provided to defray the annual cost of medicines and appliances, and in more than half of all areas of the country during 1935 this amount was not exceeded In 59 areas, however, it was exceeded and in some cases very *considerably* Manchester and Salford were again outstandingly the areas of greatest expenditure, the cost being, respectively, 54 7*d* and 55 6*d* A few of the reasonably comparable industrial areas in other parts of the country which were able to provide necessary medicines for their insured population at *very much less cost* were Middlesbrough (27 8*d*), Darlington (28 0*d*), Barnsley (28 4*d*), Dewsbury (28 6*d*) and Walsall (30 3*d*) The average expenditure per head for the country as a whole was 3*s* 1*d* and the total sum expended was £2,237,400 The report goes on to say that if it could reasonably be contended that *to spend* such a sum on medicines is necessary or desirable in the best interests of health there would of course be nothing to criticise It is believed, however, that no body of well informed medical opinion would support such a contention. On the contrary, it has been repeatedly stated by representative *practitioners* that a very large *proportion* of the present physicking of the population is wholly unnecessary and that if all doctors felt themselves free to order only such medicinal treatment as in their unfettered professional judgment was considered necessary there would at once be a spectacular fall in the total *cost of prescribing* The practitioner of the old school had a remarkable knowledge of the right use of drugs, which many of the modern practitioners with all their instruments of precision for diagnosis still need to acquire, but intelligent prescribing is very different from plural or poly-pharmacy, and insurance *practitioners* should give thought to their responsibility in this matter

PUBLIC HEALTH

INFLUENZA

THE year has opened with the worst example we have had since 1933 of the extent to which even a minor epidemic of influenza can upset the orderly working of a civilised community Fortunately there is good reason to hope that the infection will remain of a relatively mild type

The epidemic of 1933 was at about the same season In the last week of November 1932, only 33 deaths were attributed to influenza in the Great Towns by the last week of the year this number had increased nearly *tenfold to 303 and the figure continued* to rise until the end of January 1933 when it reached a weekly total of nearly 2000 deaths Thereafter the epidemic as measured by deaths, declined fairly rapidly In the present epidemic there has so far been no mortality on a comparable scale The number of deaths from influenza recorded in the Great Towns in the four weeks ending Dec 26th 1936 were 43 54 57 and 97 There was, it will be observed a fairly considerable rise in the last week of the year but the figure of 97 is not substantially above those recorded at the end of 1935 and 1933 and is below that of the first week of 1934 In each of those years influenza mortality subsequently reached no very high level. Moreover in the last eight weeks of 1936 the notifications of primary pneumonia were well below the level normal for that time of year

Of the 97 deaths from influenza reported in the week ended Dec. 26th 1936 25 occurred in London and 51 in Greater London. Outside London the number of deaths in diminishing order was as follows: Birmingham 7 Hendon and Manchester each 4 Northampton and Cardiff each 3 Croydon *Dagenham Ealing East Ham* Bolton, Doncaster Wigan Bristol Ipswich each 2 Barking Harrow Hornsey Mitcham Walthamstow West Ham Brighton Eastbourne Oxford, Barrow in Furness Blackburn, Blackpool Burnley Bury Hull, Leeds, Liverpool, Middlesbrough Rotherham, Salford Stockport Stockton-on Tees Wallasey Cheltenham Leicester Newcastle under Lyme Nottingham, Smethwick, Stoke-on Trent West Bromwich, Cambridge Plymouth Newport each 1

All classes of the community have been affected and many large establishments in London and Midland *towns report* 10 to 15 per cent. of their employees absent through illness. The incidence on certain occupations has produced the greatest dislocation Hospital nurses generally have been attacked in a degree corresponding to their exposure to infection and their inability to avoid it (but other key industries such as *operatic singing and professional* football have also suffered much and given rise to more press comment). Private nurses have been in great request and the supply has in places not been equal to the demand

TREATMENT

The Ministry of Health has issued a statement on what the individual can do to avoid falling a victim to the disease The public are encouraged to see that rooms are well ventilated and airy but not draughty and to take nourishing food and it is added it is often a good thing to take cod liver oil as well Avoidance of needless exposure avoidance of crowded places and the regular use of a gargle of dilute compound glycerin of thymol, or just enough permanganate of potash to give the gargle a pink colour are also recommended Special emphasis is laid on the need to place discarded handkerchiefs in a disinfectant solution and for persons in contact with patients to wash their hands at once after contact with the victim or with infected mucus. This common-sense statement has been widely distributed by the daily press and can hardly be without effect on the propagation of the epidemic Newspapers are also doing their part in driving home the lesson that people who insist in carrying on with their work when they should be in bed are not public heroes but public menaces

THE SITUATION IN LONDON

In London the south western area it seems has suffered more than other parts especially Paddington Chelsea and Putney it is suggested not unplausibly that infection was widely spread from large shopping centres. Islington suffered later but Bethnal Green is said still to be relatively free

Some examples may be given of the way in which the epidemic has affected the *hospital system in London* The information refers to Wednesday morning last At *St Bart's* 68 members of the staff were down *50 nursing 3 clerical 2 resident medical,* 4 works department and 9 porters (Epidemic of mild type and now declining average duration 6 days with 3 days of fever)—At *Guy's* a special ward (25) has been set aside for nurses but only one or two of the regular staff are affected (Average duration a fortnight no complications and indications that the wave is abating)—At the *Middlesex* 54 nurses have been ill and about 6 of the rest of staff (Average duration a fortnight; epidemic now abating)—At the *London* large numbers of the staff including the resident medical, are down The type is mild the duration 6–7 days and the peak seems now to have been reached —At the *Westminster* 25 nurses are ill and all the private nursing staff has been called out—which is unprecedented The rest of the staff are not affected (Influenza of mild type; duration one week; wave decreasing in intensity)—At *St Thomas's* 43 nurses out of 200 are off duty and 34 out of the 100 of the rest of the staff (Average duration 6–7 days; epidemic thought to have reached its peak.)

In the *L C C general hospitals* which normally admit *influenza cases there were on Saturday last* 18 000 occupied beds the largest number of patients these hospitals have ever had under their care at one time; but this does not necessarily imply an increased amount of illness for they are now better equipped than they have ever been to give the public the attention it wants. But as the general hospitals were so full already they were unable to cope with an epidemic of influenza On Saturday they had admitted 1010 cases of influenza and could take no more This year however there is little measles and the *special hospitals* for infectious diseases being fairly empty it was decided to set aside wards in them for influenza cases In 7 of the 9 special hospitals 500 beds have been allocated and 420 have now been filled More beds can be found but there is difficulty in finding the nurses As there was no epidemic of any infectious disease the fever hospitals were not being run on a full staff and some of the nursing and medical staff are themselves down with influenza Cases are however still being admitted on the application of any medical practitioner who reports a case which he wants to have removed to hospital The ambulance is instructed first to try the nearest general hospital and if it is full to go on to one of the special hospitals It is presumed that the pressure may decrease towards the end of the month.

The proportion of men to women victims in L C C hospitals is 40 to 60 For the most part the cases are of mild type, but in a fair number pneumonia has developed and these are being nursed in oxygen tents As a rule the acute illness lasts for 3–4 days, though there is a good deal of prostration afterwards, with rise of temperature to 101° or 102° F, irritable throat, cough, severe headache, and lumbar pain

NEWS FROM THE COUNTRY

Information reaching us from places outside London may be briefly summarised as follows —

Brighton —All ages affected Sudden onset, with headache, somatic pains, and cough, fever up to 103° F Duration 10–15 days Complications bronchitis, cervical adenitis, and diarrhœa

Thanet —All ages affected with high swinging temperature, nasal and bronchial catarrh Duration, 4–7 days in adults, longer in children, who may have secondary rise of temperature with otorrhœa

St Albans —Widespread mild influenza with a growing tendency to bronchial attack, two deaths from acute broncho pneumonia At first only elderly people attacked, now generalising Catarrhal subjects seem to escape Acute stage 2–4 days, 2–3 days pyrexia with general inflammation of the upper air passages, and superficial bronchitis, some gastro-enteritis on third and fourth days A few vivid red ear drums Disability for 2 weeks

Devon —Cases mostly among Christmas visitors, nothing that can yet be called an epidemic Symptoms headache or gastro-enteritis or both, tracheitis usual Short duration, average a week

Birmingham —Some 15 nurses off duty at the General Hospital with colds and fever lasting two days, no complications so far In three cases fatal pneumonia has followed similar colds outside

Nottingham —A leading practitioner finds conditions normal for the time of year

Liverpool Plenty of cases about but no true epidemic Symptoms severe headache, generalised pains, tracheitis, and cough No increased incidence of pneumonia. Respiratory mortality normal Sequelæ tiredness and persistent tickling cough

Newcastle upon Tyne —There is nothing that can be called an epidemic of influenza either in the urban practices of the town or in the surrounding rural country the incidence, it seems is not now greater than the normal at this time of year In the few attacks the type has been the short three day fever with muscular pains and no complications In the week ending Jan 2nd six deaths were reported from pneumonia including influenzal pneumonia (average 8 for corresponding weeks in three previous years) There is however in the area a definite epidemic, not common but troublesome, of nausea and vomiting, affecting children more than adults a 24-48 hours' illness with complete recovery, true to type and leaving no respiratory complications

Aberdeen —Epidemic only beginning All ages, children more than usual Duration 5–10 days Some short sharp attacks with pyrexia up to 104° F Younger patients often have nausea, sometimes with vomiting No serious complications

Dublin —A few cases regarded as influenza among adult males, symptoms mainly gastro intestinal No epidemic as yet

The little town of *Caerau* in Glamorgan has been severely hit although its healthy situation has hitherto rendered it immune from epidemics of most kinds School attendance has, it is stated, dropped to 40 per cent.

MEDICAL NEWS

University of London

Six lectures on statistical methods in social and economic investigations will be given by Mr J Neyman, Ph.D, reader in statistics at University College, Gower street, W C, at 7 30 P M on Tuesdays, beginning on Jan 26th Further information may be had from the secretary of the College, and changes in the hour and day of the lectures would be considered if desired by the audience

At recent examinations the following candidates were successful —

M.S

Branch I (Surgery) —John Howkins and J B G Muir (University Medal) Middlesex Hosp and E J Smith King s Coll Hosp

University of Cambridge

Dr J A Ryle, regius professor of physic in the University, has been elected to a professorial fellowship at Gonville and Caius College

Royal Society of Arts

At a meeting of this society to be held at 8 15 P.M on Wednesday, March 10th, at the house of the society, John street Adelphi W C Dr C S Myers F R S, principal of the National Institute of Industrial Research will read a paper on industrial psychology and the modern world

Royal Institution of Great Britain

Mr Julian Huxley, D Sc, will give the first lecture in an illustrated course on films in scientific education which is being given at the institution on Jan 14th, 21st, and 28th at 5 15 P M. He will deal with the use of films in biology On Feb 26th at 9 P M Lord Horder will give the Friday evening discourse, speaking on old diseases and new On March 2nd, 9th, 16th, and 23rd, at 5 15 P M, Prof Edward Mellanby, F.R S, will give four lectures on digestion and indigestion Further particulars may be had from the secretary, 21, Albemarle street, London, W 1

Post-graduate Course on Diseases of the Chest

A post graduate course on diseases of the chest with special reference to chronic pulmonary suppuration has been arranged by the Joint Tuberculosis Council and will be given by the medical and surgical staff of the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E, from Feb 1st to 6th Further information may be had from the hon secretary for post-graduate courses of the council, 8, Christ Church place, Epsom.

Royal College of Surgeons of England

Next Friday Mr Laurence O'Shaughnessy will give the first of a series of lectures which will be held at the College from Jan 15th to Feb 22nd. He will speak on the treatment of cardiac ischæmia, and Viscount Dawson will give a short opening address The other lectures are as follows Jan 18th, Mr Evelyn Sprawson, odontomes Jan 20th, Dr Russell J Reynolds, movements of the œsophagus, stomach, duodenum, and ileum during the passage of an opaque meal, Jan 22nd, Mr A S Kerr, the higher autonomic control of the hollow viscera, Jan 25th Dr S Zuckerman, tissue specificity in relation to sex hormones, Jan. 27th, Dr Zuckerman, the interrelation of endocrine and neurovascular factors in the menstrual cycle Jan. 29th Mr Cecil P G Wakeley the surgery of the parapituitary region, Feb 1st, Mr Philip Wiles, postural deformities of the spine, Feb 3rd, Mrs Philippa Martin, the effect on the eye of radium used for treatment of malignant disease in the neighbourhood, Feb 5th Mr J H Saint the BIPP method of treatment of acute osteitis Feb 8th, Mr A R D Pattison Cushing's syndrome Feb 10th, Mr D W C Northfield, headache Feb 12th, Mr F H Bentley, experimental nerve anastomosis, Feb 15th, Prof G E Gask, John Hunter in the campaign in Portugal, 1762-63 and Feb 22nd, Dr David Slome, the nervous factor in traumatic shock

Prof Gask's lecture will be given at 4 P M., all the others at 5 P M

King Edward's Hospital Fund

The King has consented to become patron of King Edward's Hospital Fund for London and has appointed the Duke of Kent its president

Society for Constructive Birth Control

A meeting of this society will be held on Tuesday Jan. 19th at 8 P.M at 26 Portland place W 1 when Dr C W Saleeby will give a lecture entitled A Plea for Summer Babies

Nichols Fellowship

Applications are invited by the Royal Society of Medicine for this fellowship which is offered for research relating to the causes and prevention of death in childbirth from septicaemia Further particulars will be found in our advertisement columns.

Course on Mental Deficiency

A course of lectures and clinical instruction for medical practitioners on mental deficiency and allied conditions has been arranged by the Extension and Tutorial Classes Council of the University of London in coöperation with the Central Association for Mental Welfare It is intended for qualified medical practitioners who are concerned with the care of subnormal or abnormal persons. The first part of the course will be held from April 12th to 24th and the second part will be given in the autumn Further information may be had from Miss Evelyn Fox, University Extension Department University of London W C 1

Conference on the Accredited Milk Scheme

A conference to discuss the administration of the Milk (Special Designations) Order 1936 with respect to accredited milk, will be held by the Royal Sanitary Institute on Thursday Jan 28th at 2 P.M at 90 Buckingham Palace-road London S W Mr Thomas Baxter chairman of the Milk Marketing Board, will preside and the discussion will be opened by Dr W G Savage medical officer of health for Somerset Mr F W Medlock chief veterinary officer for Essex; Mr H F Long chief sanitary inspector for Hereford; and Mr W T Price agricultural organiser for Wiltshire

Order of St John of Jerusalem

The following promotions in and appointments to the Venerable Order of the Hospital of St John of Jerusalem have been sanctioned by the King —

As Knight—Sir Louis Knuthsen K.C V O O B.E M D Godfrey Martin Huggins F R C S M.P Lieut. Colonel Alexander Robertson Falconer C.B E. V D M B and Sydney Letts Dawkins M B

As Commander—William Douglas Kirkwood, M.D Lieut -Colonel Henry Woolmington Webber M.D F R C.S E. Leonard Erasmus Ellis, M.D Colonel John Arthur Hopkins Sherwin V.D M D Surgeon Vice-Admiral Sir Robert Hall K C B O B E M R C.S and John Newman Morris M B

As Associate Commander—Lieut Colonel Sir Hassan Suhrawardy O B E M D F R.C.S.I

As Officer—Gerald Holroyde M C M R C P Ernest Jones M B Captain Harold Francis Joseph Norrie M.B Robert Vickers Clayton, M B Lieut Colonel Lavell Hall Leeson M.D Lieut Colonel Wilfred Vickers D.S O V.D M.B Colonel Herbert Henry Ernest Russell O B E. NOTES, COMMENTS, AND ABSTRACTS

THE PATHOLOGY OF THE TOXÆMIAS OF PREGNANCY

A SURVEY*

By Robert Coope M.D B Sc Liverp
M R C P Lond
HON ASSISTANT PHYSICIAN LIVERPOOL ROYAL INFIRMARY
VISITING PHYSICIAN MILL ROAD INFIRMARY LIVERPOOL

Those who have explored the literature of the toxæmias of pregnancy will I think agree that there is hardly a field in medicine which even now presents a more confused and untidy scene Theories classifications speculations galore—one emerges—

> Like one that hath been stunn d
> And is of sense forlorn,

but if at the end of it one is indeed a sadder man it is very unlikely that one rises up a wiser man I wonder if what we are suffering from here is an excess of specialism—(dare I say it ?) that too often obstetricians and biochemists working in the obstetrical field without a large enough background of general medicine get their proportions wrong confuse the issues with a vocabulary of their own and overlook *straightforward diseases just because they occur* in and are modified by pregnancy ? There is only one cure for this confusion—namely to get back to pathology and not be satisfied until names and labels are given a clear pathological content It is true that names and labels may have to be used as stop-gaps even when we are not clear as to their pathological content but they are dangerous because they may easily lull a man into the belief that he knows more than he really does I need only remind you that a word like erythema sounds much more weighty and scientific than red rash

Boswell gives an account of a certain breakfast party in Edinburgh to which Dr Blacklock was invited to meet Samuel Johnson Dr Blacklock spoke of scepticism in religion with apparent uneasiness as if he wished for more certainty the great man in reply encouraged the blind Bard to apply to higher speculations what we all willingly submit to *in common life* Take the case said he of a man who is ill I call two physicians They differ in opinion I am not to lie down and die between them I must do something

Very well then let us see with what we are really faced in this group of illnesses called the toxæmias of pregnancy At the outset we must be careful not to beg the question by assuming the word toxæmia to have an exact defined and constant meaning and it is well to remember that in these diseases no specific toxins have ever been discovered There are those illnesses which occur in the earlier months of pregnancy—morning sickness (we ought to include this for to be sick is not normal) and hyperemesis gravidarum and there are those illnesses which mainly show themselves in the later months—so called albuminuria of pregnancy nephritis eclampsia accidental antepartum hæmorrhage and damage whose main incidence appears to be on the liver—acute and subacute yellow atrophy of the liver We must bring ourselves to be sceptical of many of these as adequately defined clinical entities and try to analyse the pathology behind them

But these illnesses are occurring in a pregnant woman and our analysis is made against the background of pregnancy with its inevitable and insistent facts of a growing ovum a maternal organism subjected to new and searching calls on the normal physiological processes and separating the two a placenta which for all its complexity is in essence a semipermeable membrane between the two blood circulations There is therefore a physiology of pregnancy to be taken into account and as Barnes says Gestation tests the integrity of every structure of the body May I remind you of a few of the important physiological changes in pregnancy which may have a bearing on our subject ? There are alterations in the activity of the maternal ductless glands ; alien proteins may invade the blood-serum (and form a basis for the Abderhalden reaction) and *there is a leucocytosis which Dietrich (1911)* attributes to a reaction on the part of the mother to the ovum and its products There is a large and prolonged call upon building materials and if the mother does not get enough food she will attempt to build up fœtal material from her own tissues The call on maternal calcium may cause decalcification of teeth or even of bones, and the need for iron is great also The liver may lose a good deal of its stored glycogen, and there is evidence from animal experimentation that towards the end of pregnancy there is a physiological fatty infiltration of the liver (Coope and Mottram 1914) Pregnancy involves the adaptation of the maternal organism to a fœtus and though it may not yet be possible to pick out the most vital of the mechanisms of this adaptation it may be that the strain involved is an important factor in the development of these toxæmic illnesses.

MORNING SICKNESS IN EARLY PREGNANCY

The fact that this symptom often occurs before the patient has realised that she may be pregnant suggests that it is not primarily a neurosis as some maintain though anxiety may be a contributory factor The embedding of the ovum is associated with liquefaction of the endometrium by trophoblastic ferments with resulting decomposition products There is no doubt that even in early pregnancy a real disturbance takes place in the maternal organism long before large calls have been made on it for building up the fœtus There are plenty of theories but no proved explanation of what is happening here It is, however suggestive to note that in the presence of an abnormal ovum or of a hydatidiform mole the sickness is apt to be much more severe

If vomiting persists there will be a considerable loss of fluid accompanied or not—usually not—by loss of chloride from the stomach moreover with starvation the liver will lose a large portion of its store of glycogen and ketosis will develop The pregnant woman in any case tends to get carbohydrate starvation and she reacts very much as the child does when attacked by ketosis and dehydration Prolonged starvation of this kind results in a mobilisation of the fat reserves and a fatty infiltration of the liver ; and a fatty liver without glycogen reserves is a liver much more susceptible to the effects of various poisons

So far we are dealing with a vicious circle of vomiting starvation glycogen depletion and dehydration and we find their manifestations in blood and urine—

---

* A paper read at a joint ordinary and pathological meeting of the Liverpool Medical Institution on Nov 12th 1936

acetone bodies and a high ammonia ratio in the urine, and a relative increase of non protein nitrogen in the blood If these patients are not properly treated and the carbohydrate deficiency made good they may die, and the post mortem appearances are those of death from starvation

HYPEREMESIS GRAVIDARUM

When the vomiting is severe and persistent enough to be termed pernicious—hyperemesis gravidarum—it may be, as some declare, that the original sickness is being maintained and enhanced by a neurosis, or that adequate treatment of starvation is not being supplied , but in the severest cases—and they are rare—it is clear that profound tissue damage is taking place Where death occurs, post mortem examination reveals not only the evidences of carbohydrate starvation, but actual necrosis of the liver cells, and perhaps scattered hæmorrhages also Here, surely, we are dealing with a condition of hepatic damage in which are involved to a more or less degree the two complementary factors of a liver more liable than normally to cell injury and of some outside poison We have already seen that a glycogen depleted liver is less resistant to poisons, and that pregnancy makes a heavy call upon the body's store of glycogen These facts seem to me to make unnecessary the present day speculation, vague and unproved, that hyperemesis gravidarum is a deficiency disease, due to the insufficient intake of some undefined substance or substances necessary for the maintenance of maternal and fœtal metabolism Is the slight apparent toxic effect of the early ovum upon the mother enough to account for a poisoning lesion in a susceptible liver ? It is difficult to think so, because the condition is so infrequent as to show that in spite of pregnancy the hepatic reserves are usually adequate It is much more likely that the main factor is some outside poison which damages the liver cells, bacterial or chemical , and I suggest that here we ought to think more of the possible causes of hepatitis and less of the pregnancy itself The onset of pernicious vomiting is usually early in pregnancy, in the second or third month , and there is one line of inquiry which perhaps merits more attention than has hitherto been given to it I wonder in how many cases the poison is chemical, from some abortifacient or other ? I recall a patient whom I saw in consultation, three months pregnant, seriously ill, though she did not die , she had hepatitis, with an enlarged tender liver, persistent vomiting, and subicterus She later confessed that she had done her best "by taking things" to procure an abortion The same chemical factor may explain some at least of the cases of acute or subacute yellow atrophy of the liver, seen in the later months of pregnancy Indeed, if it is true as is nowadays suspected, that there is a large amount of attempted termination of pregnancy, it is perhaps surprising that more of these cases do not occur , that they are so rare speaks volumes for the hepatic and renal reserves of even the pregnant woman, making it appear even less likely that the normal ovum produces any very serious "toxins"

To sum up vomiting is a symptom only, even in pregnancy and therefore it would be wise to drop the term hyperemesis gravidarum in favour of more pathologically minded definitions—as for example, carbohydrate depletion neurotic vomiting, hepatitis, and in some cases even in early pregnancy, chronic nephritis To attempt this would at least ensure a constant challenge to exactness of diagnosis

Let us now turn to the "toxæmias" which manifest themselves mainly in the later months of pregnancy Here again there is a widespread lack of agreement on classification and terminology, and one comes across labels such as the kidney of pregnancy, albuminuria of pregnancy, low reserve kidney, albuminuria due to pregnancy, recurrent pregnancy toxæmia, and so on, which remind one of a similar orgy of classification sometimes seen in studies in nephritis I propose to confine what I have to say mainly to albuminuria occurring in pregnancy, nephritis, and eclampsia

ALBUMINURIA

Albuminuria is but a symptom and not a disease entity , but because taken even by itself it is so often a danger signal, routine examination of the urine for albumin sometimes so takes the attention of the practitioner that he may forget to add certain other simple but important investigations—the examination of the urinary deposit, for example, for casts, red blood corpuscles, or pus cells Albumin in the urine may come from admixture with vaginal secretion, from various inflammations or ulcerations of the bladder or ureter or a pyelonephritis, or from damage to the kidney cells themselves, that is to say to the renal barrier between circulating blood and urine, with increase of its permeability either from inflammation, as in nephritis, or deficient oxygen supply, as in congestive heart failure A catheter specimen is therefore always advisable, and if albumin is present, the finding of pus cells, crystals, red blood corpuscles, or casts of various types will help to define what is the underlying lesion Moreover the persistence or disappearance of these various constituents over a proper period of investigation will again throw light upon the nature of the trouble, and reveal whether the obvious damage is temporary or permanent

NEPHRITIS

Nephritis in pregnancy does not differ in essence from nephritis apart from pregnancy, though there are some special considerations in pregnancy which are worthy of mention My own view is that the only really practical classification of nephritis is into the two categories of acute and chronic Whatever the cause, the important fact is the degree of damage to the standing army of approximately ten million nephrons which make up the architecture of the kidneys When sufficient numbers of these units are put out of action, then the remainder may be able to meet normal calls on excretion, but will fail under strain , if more units still are destroyed the survivors will be unable to meet even the minimum of normal demands The damage to the individual nephrons may, of course, be only temporary, or it may be final and permanent , some may be put out of action for a time, yet may live to fight again In any patient, pregnant or otherwise, renal failure may be due to a single attack of acute diffuse nephritis, or to a summation of many less extensive lesions whereby fewer and fewer nephrons are left alive and intact It is common medical experience to find that an apparently sudden attack of acute nephritis is in fact superimposed upon a previously unsuspected yet pathologically quite extensive chronic nephritis or that chronic nephritis of what must be long standing does not become clinically obvious until there is some unwonted strain on the whole organism There seems to be no doubt that pregnancy is one of these strains—indeed someone has called it the acid test of renal function , and as might be expected, increasing age and multiparity predispose to the breakdown of hitherto adequate renal function I do not propose to review here the almost frightening mass of literature on the subject; the curious reader will find an admirable compendium of it in Dame Louise McIlroy's recent book The Toxæmias of Pregnancy' There are two studies however which bear closely on the point I wish to make One is by G F Gibberd (1934) on the relationship of the toxæmias of pregnancy to nephritis in which he sets forth the results of a follow up of cases of albuminuria of pregnancy In it he advances the theory of occult nephritis to explain the recurrent nature of this so called toxæmia in certain patients this nephritis being the result, he thinks and not the cause of the toxæmia; though there seems to me no valid reason why in some cases at least the nephritis should not be occult even before the onset of the first attack of albuminuria

Browne and Dodds (1930) were able to produce just such an occult nephritis in rabbits by the injection of uranium nitrate or sodium oxalate They then observed the animals through a succession of pregnancies. In many of them they noted a recurrent albuminuria of pregnancy appearing in the second half of pregnancy disappearing entirely in the intervals between the pregnancies In these intervals the animals seemed to be normal, and there were no changes in the blood chemistry to suggest any kidney defect Nevertheless their kidneys showed microscopical evidence of actual nephritis all the while then they had a mild degree of chronic renal damage which was exacerbated under the strain of pregnancy and afterwards the animal settled down again to an apparently normal clinical picture But with each attack we must see in imagination more casualties to the already depleted forces of the fundamental renal units Sooner or later as Gibberd's figures indicate these casualties to the nephrons will end in such depletion of the reserves that chronic nephritis becomes clinically obvious If anyone should ask What is the exact mechanism of the damage to the renal units in pregnancy? it might be the better part of valour to reply with a counter question What anyway is the exact mechanism of damage in cases apart from pregnancy? All too often it is impossible to pin down the damaging factor In pregnancy however there is this suggestive fact the longer so called toxæmic albuminuria exists before the uterus empties itself or is emptied of its contents the more likely is the development of a persistent nephritis

In summing up this section I would emphasise the following points damage to the kidneys means for practical purposes damage temporary or permanent to individual nephrons Chronic nephritis whether clinically obvious or not is apt to be made worse by pregnancy though the exact mechanism of this damage is not clear There is evidence that underlying nephritis predisposes not only to death of the fœtus and abortion but also to toxæmias of pregnancy —some cases of eclampsia for example and some cases of accidental antepartum hæmorrhage There is also evidence that the various toxæmias of pregnancy themselves may leave behind a trail of fatally damaged renal units and determine the development of a clinically obvious chronic nephritis

ECLAMPSIA

The theories of the causation of eclampsia are legion; here are some of them auto intoxication toxæmia from fœtal elements or fœtal metabolites or placental products endocrine disturbances faulty diet maternal metabolic disturbances, infections reactions of agglutination or hæmolysis anaphylaxis mammary toxæmias alterations in amniotic fluid We had better turn straightway to the known pathological appearances of patients who die from the disease The liver is pale with scattered red areas of hæmorrhage both in the parenchyma and under the capsule There is often thrombosis of intrahepatic portal vessels with necrosis of the liver cells particularly at the periphery of the lobules. The kidneys also show scattered areas of small hæmorrhagic infarcts with diffuse though usually not severe glomerulitis narrowing of the renal vessels and degenerative changes of varying intensity in the convoluted tubules On the whole the renal changes are mild There may be scattered hæmorrhages and necrosis in the heart muscle and similar patches of hæmorrhage and necrosis in the brain The clue to the picture lies in a widespread capillary injury with consequent thromboses and interstitial blood extravasation and œdema throughout the tissues the necroses which occur in various organs are almost certainly the results of this primary vascular damage

With this pathology in mind recall the more important clinical features of the disease—the raised blood pressure the œdema the convulsions the coma Are we not dealing with a condition analogous to that which in general medicine we recognise as the hypertensive cerebral attack a complication particularly of acute nephritis in young persons or in older patients of raised blood pressure which may be either primary or secondary to chronic nephritis? Volhard (1931) calls this condition acute pseudo uræmia and thinks that eclampsia is a typical example of it. A raised blood pressure is the determining factor with damage and therefore increased permeability of capillary walls and in some cases areas of angiospasm ischæmia and following this diapedesis of red cells through the vessel walls In either case there is œdema localised areas of extravasated blood and in the severest cases consequent cell necrosis from pressure In this way there develop focal lesions in organs like the liver kidney brain and retina Whether eclamptic convulsions are associated with a high or normal non protein nitrogen content of the blood will thus depend on the ætiology cases which complicate an old-standing nephritis will show an increase but it is clear that cases arising as it were de novo may not In confirmation of the vascular basis of eclampsia there are some fascinating observations by Haselhorst and Mylius (1928) They watched the optic fundus in a case of eclampsia from hour to hour and took photographs At first there was intense spasm of the retinal vessels; then as the blood pressure rose hæmorrhages and exudation appeared with œdema of the retina After the uterus was emptied the spasm of the vessels passed off the œdema cleared and the retinal exudate slowly resolved The œdema of the retina may be so abundant that it may as Doggart says push the retina right forward without folds until it looks like a full blown sail but as one might imagine if the above is a correct pathological description the prognosis in this eclamptic detachment of the retina is quite good provided that there is adequate treatment of the eclampsia

What will happen to the liver and the kidneys will depend on the extent of the cell damage and on how long the ischæmia and œdema persist It is clear that there is a serious danger of permanent renal damage even in the cases which recover and there is enough evidence to show that this does in fact happen in a large number of cases

But what precipitates this form of capillary damage and the hypertensive cerebral attack? The fact that primiparæ suffer in the proportion of about 8 to 1 as compared with multiparæ suggests that the majority of the cases are not due to primary or secondary hypertension, but to some acute vascular disturbance with increased permeability of thin-walled and comparatively young vessels Immediately the possible explanation of it as an allergic manifestation comes to mind And I think that it is something more than a groundless speculation For if we turn to the diffuse glomerulonephritis associated with streptococcal infections such as tonsillitis or scarlet fever, there is a considerable time lag between the onset of the infection and the onset of the nephritis, suggesting that the process is not quite as simple or straightforward as might be thought Work which has come from Fahr and his co workers, and from Arnott, Kellar, and Matthew (1936) does bring experimental support to the theory that this form of acute nephritis is an allergic phenomenon, due to an intense antigen antibody reaction in a patient with a streptococcal infection Is eclampsia after all just such an allergic illness? If so, what is the antigen, and whence comes it? Does it come from the fœtal side of that complex separating membrane, the placenta? And, if so, is it because that semipermeable membrane is damaged, and so lets through some substance to which normally it raises an impassable barrier? Once more we find ourselves asking questions which as yet have no answer, but they are questions which have a basis of reason, and therefore they may be asked with some degree of hope

I have said little about biochemistry in this survey, for my view is that the proper interpretation of whatever biochemical findings are made in blood and urine cannot be clear until there is a sound conception of the pathological basis of these various diseases

THE AMERICAN IDEAL

THESE are times when citizens of the United States and the British Commonwealth should dwell on the aspirations they share rather than on their differences of accent Just as anatomy can sometimes be learnt best through embryology, so the nature of a nation may be more obvious in its history than in the complex body it presents to contemporaries Mr Arthur Bryant has used an embryological approach in his description of "The American Ideal,"[1] for he traces its development by showing how it has been expressed in the past 150 years by eight different men—Jefferson, Lincoln Emerson, Whitman, Theodore Roosevelt Walter Page, Vachel Lindsay, and Alan Seeger "The dream of the plain man seeking bread in the wilderness" as he did in the old days, runs through the history of the States To Jefferson society must be kept as simple and unrestricted as possible to Lincoln government was no office problem but an affair of the man in the street, who must have a fair chance in the race of life The American ideal was born in revolt against the dead hand of custom and privilege, and if the individualism of "the independent farmers and freeholders" to whom Jefferson entrusted the liberties of the future no longer seems a sufficient basis for national life it must at all costs be modified rather than destroyed By *making the reader see and sympathise with the* aims of these great men Mr Bryant demonstrates the importance of the American experiment both yesterday and to day

WORK AND RHYTHM, FOOD AND FATIGUE

THIS is the title of a pleasant little book,[1] consisting of a preface and epilogue and five essays upon Nutrition, Fatigue, Emotion and Stress Rhythm, and Nutritional Adaptations to Stress and Fatigue Each of the subjects is treated in relation to modern life, and the trend of recent research is indicated The author claims no authority either by word or manner, and his interpretations of experimental evidence, if not "cast iron" at least lead to sensible conclusions and are given and must be taken as opinions There is no fanaticism in his ideas about the rhythms of life in general, and its very absence helps to persuade the reader of their importance Neither is there anything militant about his advocacy of various reforms, and one reads with relief that he actually detects some favourable trends in our modern civilisation. Besides being instructive, the book is a plea for the recognition that it is the simple things, like food and rest, which make life worth living—"nutrition is not of bread alone, but rest, rhythm, the absence of din and hurry, and the unpolluted air and waters of unspoilt countrysides are factors in it too"

ADDRESSES AND ORIGINAL ARTICLES

TUBERCULOUS DISEASE OF THE ABDOMINAL LYMPHATIC GLANDS

BY G H COLT M B B Chir Camb F R C S Eng
CONSULTING SURGEON TO THE ABERDEEN ROYAL INFIRMARY
AND
C N CLARK, M B Aberd F R C S Eng
ACTING MEDICAL DIRECTOR OF THE ANGLO SWISS HOSPITAL, ALEXANDRIA

THIS paper gives the results of an investigation into the symptoms and signs exhibited by patients suffering from the later stages of tuberculous disease of the abdominal lymphatic glands The patients were admitted into a ward in the Aberdeen Royal Infirmary under the care of one of us (G H C) during the ten year period 1923 to 1932 The series is a consecutive one of 239 cases 127 being male and 112 female patients An effort has been made to trace and examine every patient and has been successful in that 207 have been traced and 118 examined.

Caseous Mesenteric Glands

During the ten years 38 patients with caseous mesenteric glands were operated on some of them for unrelated conditions during acute obstruction or for acute appendicitis Of the 50 cases dealt with by the late Mr Carson (1918) 44 were of the caseous variety and 6 calcareous He appeared to be strongly of the opinion that the caseous glands required excision The glands which demand operation therefore are the caseating glands and those alone Many surgeons agree with this because of the danger of complications arising when operation is not undertaken

SYMPTOMS

The duration of symptoms was much less than in the calcareous type being usually stated either in months or weeks rather than in years Abdominal pain was always the first symptom In the majority of patients it was in the right side of the abdomen or in the right iliac fossa There was usually a history of the pain being generalised across the abdomen or peri umbilical initially and later settling in the right iliac fossa but 5 patients had pain in the left side of the abdomen There was occasionally a history of radiation across the abdomen to the other side—mostly from right to left; to the back; to the right leg to the labium (2 cases) and to the shoulder in 1 case There was apparently no relation between exercise and the pain only one patient stating that the pain was worse after exercise; 2 patients were relieved on resting The pain was variously described as sharp shooting stabbing like toothache severe sharp sharp stooning spasmodic dull ache dragging steady and like a stitch In one case the pain was sufficiently severe to double up" the patient The patients with the longer histories had usually had a series of attacks of short duration with an interval of a month or two between them The attacks tended to become more severe and were often accompanied by nausea and vomiting There appeared to be a definite tendency to constipation

PHYSICAL SIGNS

In all cases except one there was some tenderness in the abdomen situated almost invariably in the right iliac fossa Hyperæsthesia and increased tonus of the muscles were uncertain and tended to be present only in the cases complicated by appendicular inflammation A mass was palpable in 8 of the cases In 3 the mass was in the right iliac fossa in 2 in the left iliac fossa in 1 to the right of the umbilicus; and in 1 to the right of the left kidney Lockwood's sign (Colt 1932) which is of great value in the diagnosis of adhesions in the cæcal region was recorded as positive in 4 cases 3 of these had appendices which were adherent to the cæcum by bands the fourth had adhesions of the omentum to the peritoneum of the right iliac fossa Hyperæsthesia over the right lower quadrant was more diffuse and less intense than in appendicitis.

Ketosis —It was noticed that in the great majority of the subacute and acute cases (both caseous and calcareous) the patient's breath smelt strongly of acetone In surgical cases this is often due to excessive vomiting with upset of the carbohydrate metabolism But in the majority of the cases vomiting had been absent or infrequent When subacute it was often possible to decide by the presence of ketosis that the case if not one of intestinal obstruction could be left for medical treatment and operated on later at a safer period The degree of ketosis in acute appendicular obstruction of equivalent duration is not nearly so pronounced and in fact is often absent

Pyrexia —In some of the more extensive and acute cases of caseation and more especially in younger patients the temperature was raised This was discussed at the Medical Society after Carson's paper Gauvain supported Carson that there was a rise in temperature in only a few cases while Warren Low and others were emphatic that the cases they had seen had continued pyrexia Carson in reply suggested that cases with pyrexia were due to systemic tuberculosis with peritoneal extension Braithwaite (1925) makes the statement —

> It has been suggested that an acutely inflamed gland causes a rise of temperature whereas acute appendicitis does not How many men in general practice will agree with this? It is known that almost every painful condition in a child gives rise to an elevation of temperature A temperature above 100 F would indicate the condition to be tuberculous adenitis rather than appendicitis

This is clearly put by John Fraser (1022) Fever introduces the illness while in appendicitis temperature is comparatively late in its appearance

Marshall (1028) in a study of 46 cases of simple ileo-cæcal lymphadenitis finds symptoms very similar to those given here

Radiological examination was made in 18 of our cases and in 11 of these areas of calcification were seen suggestive of glands that had calcified or had begun to calcify Carson only once observed a vague shadow of a caseating mass by radiography but he was describing a series of younger patients in whom calcification in other glands had not taken place At that time (1018) radiological apparatus and technique were not so efficient as they are to-day In our series there were a number of caseous cases in which calcified glands were also present The fuzzy mottled appearance of the latter is typical (see Fig 3)

None of the writers on the subject of tuberculous mesenteric adenitis appears to have suggested that X ray examination repeated at intervals would be of value in estimating the chances of the patient's recovery The appearance of well-calcified patches in a radiogram of the abdomen, where there were none previously, would undoubtedly be a good prognostic sign

Diagnosis —Many of these patients were admitted as cases of acute or subacute appendicitis and the figures show that the two conditions frequently coexist In diagnosing between them the points for and against each may be summarised in the following way The gland patient may show the several characteristics of either of the two main types that have long been recognised as tuberculous The sanguine type with her quick intelligence, fine regular features, clear skin, long lashes, and downy hair on the back and arms, and the phlegmatic type with slower intellect, thick skin, and podgy features In the gland patient there is commonly a characteristic history of previous attacks of pain, which may have been as severe as the present one In the appendicitis patient the pain is more severe, lasts longer, tends to settle in the right iliac fossa, and is seldom felt on the left side In the gland patient there may be nausea and possibly vomiting, in appendicitis vomiting is almost certain to occur In the early gland case the temperature may be raised to 100° F, sometimes more, whereas in appendicitis the temperature will not be raised until several hours have elapsed In the early stages the pulse rate will offer little help, but in the late stages it will be greater in appendicitis than in the gland case The leucocyte count in the early stage of each is low and will not rise appreciably in the gland case, but will soon reach 15,000 to 30,000 in appendicitis The breath will smell strongly of acetone in the gland case, but not in appendicitis until vomiting has been frequent If ketosis is present a general anæsthetic given for making a satisfactory rectal examination would be contra-indicated The area of hyperæsthesia is more diffuse and less intense in the gland than in the appendicitis patient This may be due to the situation of the gland—high up in the mesentery compared with the appendix—allowing it to act on nerve fibres distributed more extensively Should radiography be possible and positive, and the patient under skilled observation, and should other signs be fairly typical, it would be advisable to adopt the course of clearing the bowel with an enema, giving glucose by the mouth and rectum, waiting a few hours and repeating the leucocyte count Such a course sometimes allows operation to be undertaken at a less dangerous time or avoided altogether In case of doubt it will be safer to operate through a right paramedian instead of through one of the smaller incisions

CLINICAL PATHOLOGY

In reviewing these 38 cases the most striking fact is the large number which had an associated lesion of the appendix There were 18 cases with some involvement of the appendix—not old signs of inflammation but active acute inflammation or congestion, in almost half the total number Either the appendix was giving rise to the symptoms for which the abdomen was opened or the appendix inflammation provided the little extra stimulus for the gland to break down and become caseous This last explanation should not be taken to mean that all such glands require an added toxæmia from appendicular inflammation to cause caseation. Both explanations seem to have claims to truth and both are probably true Morley Fletcher (1929a) writing of children describes an "acute localised form" of tuberculous peritonitis This form which he calls "appendicular" or "ileo cæcal," is associated with caseous glands in the ileo-cæcal angle and an injected swollen appendix He advises removal of the appendix and of the adjacent mass of glands The appendix was examined microscopically for evidence of tuberculosis in 15 of our cases In none of them was any evidence of tuberculosis found. Four of the glands removed were examined microscopically and all were tuberculous

Localised tuberculous peritonitis —In caseous cases danger arises when small areas of inflamed peritoneum become attached to adjacent coils of gut o to the omentum. When the inflammation subsides the adhesions may either contract, stretch, or separate completely or the omentum may become stretched out into a tenuous band, which eventually gives way altogether There have been many instances of this and in one case the gland and its adherent omentum were removed in one piece On the other hand, when a loop of gut adheres to the mesentery and becomes twisted or kinked or leaves an opening through which another loop of gut can pass, strangulation may occur The omental band may produce a mechanical obstruction by pressure on the gut Inflammatory changes in the mesentery itself may shorten it and so bring about conditions favourable to the development of a volvulus or may cause axial rotation of the gut as is referred to under the obstruction series

Perforation of caseous glands —Perforation of a gland must be a fairly frequent event With perforation the risk of acute general tuberculous peritonitis is obviously very great Widespread bowel and omental adhesions are sometimes instances of recovery from this condition, with subsidence of activity and without persistent ascites Some cases of acute general tuberculous peritonitis also represent a proportion in which the patient was not able to resist such a sudden infection In the earlier stages of both varieties there would be free fluid in the abdomen, and the slight rigidity and tenderness associated with it might easily lead to the diagnosis of an attack of mild appendicitis In this connexion it is interesting to note that Fletcher (1929b) states that *trauma* may have a direct relation to the onset of tuberculous peritonitis A blow on the abdomen when the muscles were not on guard might easily rupture a caseous gland There were 2 cases of perforation in our series In neither was there a history of injury From what has been said it will be evident that these two cases do not represent the true incidence Their histories are briefly as follows

A male aged 29, with an eight hours' history of generalised abdominal pain coming on immediately after dinner and later settling under the left costal margin There was a large amount of free fluid in the abdomen and a large perforated tuberculous mesenteric gland with thickened and calcified walls The gland was incised and drained The appendix was not removed He felt in much better health 19 months after operation, and had gained 1¾ in weight

A male aged 20 a farm servant, was admitted after several attacks of abdominal pain during the previous five months For the last five days the pain had become worse He vomited on the day of admission He was flushed had a dry tongue, foul breath a temperature of 101 5° F, and a pulse rate of 104 The abdomen was rigid and slightly tender all over A large suppurating mass of tuberculous mesenteric glands was found at operation The mass had perforated filling the abdomen with pus The appendix was gangrenous There was generalised miliary tuberculous peritonitis The perforation in the mass was closed, the abdomen mopped out the appendix removed and the abdomen closed The appendix on section showed miliary tubercles of the serosa and the pus from the mass and the exudate was sterile and negative for tubercle bacilli by staining methods. When seen 7 years later the patient was in better health than before had gained in weight and had been relieved of his symptoms He still had frequent pains in the left hypochondriac region which at times almost incapacitated him and were sufficient to cause him to come up to be seen on two occasions with a view to further operative treatment

It seems that the first patient overcame the tuberculous process completely and the second now suffers occasionally from the effects of intra-abdominal adhesions.

TREATMENT*

Surgery —In 29 of the 38 cases (more than three quarters) it was possible to excise the affected glands This does not mean that all the calcareous and enlarged glands were resected in any one patient usually all the larger and caseous glands were excised and any calcareous glands which were considered likely to give rise to trouble in the future When it was not possible to excise the glands completely either on account of the bad condition of the patient or from the position in the mesentery or on account of the size of the mass with its surrounding induration and œdema, evacuation with a spoon or scoop was resorted to after an incision had been made into the capsule There were 5 such cases a sixth might be added where the procedure was to incise the mass swab it out and leave in a drain because secondary infection was suspected Evacuating the contents of the gland capsule does not appear to be the ideal procedure but it is often the only one compatible with safety

Sinus formation is commented on by Braithwaite and he advises against the removal of a gland near the mesenteric border in case a fæcal fistula results In a good coloured picture of such a case the segment of gut near the gland is shown inflamed and somewhat contracted He recommends isolation by omental graft when removal is difficult.

Therapeutics —It has been suggested in the past that attempts might be made to hasten calcification by giving calcium salts More recent work on the calcification of tubercles in experimental animals shows that irradiated ergosterol or vitamin D has a great effect in the promotion of calcification of caseous tubercles in rabbits (Levaditi and Li 1931) and guinea pigs (Jampolis and Witt 1933) The beneficial effect of sunlight both natural and artificial in the general treatment of the disease may be largely due to this process of calcification sealing up the tuberculous areas It may well be that the degree of calcification in the other areas of the body liable to tuberculosis and the benefit likely to ensue from ultra violet radiation are very closely related—e g calcification in the lung lesions is relatively rare and ultra violet radiation is understood to be contra indicated in phthisis Jampolis and Witt are cautious in so far as they point out the fact that the conditions in the animals experimented on are not directly applicable to man A warning may be noted here in the treatment of caseous patients by ultra violet light or sunlight Carson (1926) quoted Rollier in an excellent article on tuberculous peritonitis to the effect that sun treatment produces its best results in the ascitic type but in the caseous type a congestive reaction accompanied by vomiting and fever may occur Vitamin D increases the serum calcium and phosphorus and both are then retained in greater quantities in the body Milk is the most important food containing calcium Absorption of calcium is promoted by an alkaline digestive juice Practically therefore the patient should be given vitamin D exposed to ultra violet rays and encouraged to drink milk with some sodium bicarbonate some time before meals The mineral salts are supplemented, if need be by the administration of calcium and phosphorus As in cervical tuberculosis it will be obvious to anyone who has had a long experience that there is much uncertainty in any method of palliative treatment In some cases a diagnosis is not possible in the abdominal cases until the abdomen is opened. Radical treatment at the time is then more appropriate Glands which are merely swollen should not be removed A piece may be taken for biopsy and the abdomen closed

TABLE I

Results of Treatment

Traced.	Untraced	Excellent	Fair	Poor	Died
36	2	27	3	1	5

It seems also that when a preoperative diagnosis of caseous glands has been made, the safest treatment is removal. Such patients are liable to develop grave complications at any time if nothing radical is done One should however avoid operation if repeated radiological examination shows that calcification is actively progressing From the suggested relationship between a diseased appendix and caseation it seems that the appendix should generally be removed

The results of treatment in the 38 cases are shown in Table I

Calcareous Mesenteric Glands

This part of the paper is based on a study of 201 consecutive cases summarised in Table II

TABLE II

Summary of Cases with Calcareous Glands

Nature of case	Traced	Untraced	Males	Females	Total
Calcareous cases	144	2	91	75	166
Reoperation cases	31	4	15	20	35
—	175	26	106	95	201

It has been assumed that the calcareous glands were at one time caseous and have run their usual pathological course In the absence of any definite information we may take it that the majority of glands are well on the way to complete calcification at the end of a year after they have been infected with tubercle many have probably commenced to calcify within half that time Radiological evidence in a series of patients of different ages would be most valuable if it could be obtained

The dangerous period —During a period then of a few months to a year or more each caseous and calcifying gland may be a source of danger This does not necessarily correspond with the period during which the patient is actually in danger One or two glands may caseate and commence to calcify Others may break down some considerable time after the first The cycle is gone through again with another danger period to the patient There is no doubt about this happening as in some of the cases caseous glands coexisted with calcified gland Clinically this repeated cycle was recognised by Hutchison (1925) when he wrote:—

> “I do not think one has a right to say that a case is completely cured simply because after a few months the

symptoms have not recurred The disease is apt to remain latent for a considerable time Such a child may, perhaps, get an attack of diarrhœa, or other slight illness, which pulls him down and, his resistance for the time being lowered, the process flares up again"

The sequence would be an intestinal upset, increase in caseation with more rarely the bursting of a caseous gland, and the onset of a more or less localised tuberculous peritonitis The second attack would tend to be of slighter extent because of the adhesions left by the first, and of less severity on account of the resistance developed by the patient

Effects of natural cure—That a natural cure by complete calcification occurs in a very large percentage of cases must be obvious In many cases the cure is complete from the patient's point of view—he has no symptoms whatever The glands are in a position in which they are not liable to press on any of the important intra abdominal structures They are of such a size and shape that they do not rub on adjacent structures when strenuous movement causes the abdominal contents to change their positions A possible or, judging by operation cases, a probable exception is when there is a spike of calcareous matter sticking out of the gland, or when the surface is crenated as is often observed Even small masses of this kind give rise to symptoms It seems therefore that obese subjects would be less liable to suffer than the thin, since the glands would be surrounded by fatty beds which would tend to distribute their pressure more evenly over a larger area These calcareous masses must have very little tendency to contract, once calcified, their shape and size tend to remain the same, a fact very much in the patient's favour, or had healing taken place by fibrosis there would be a continued contraction of the area with a greater liability to the narrowing of the blood vessels, to the obliteration of lymphatics, to pressure on nerves, and to distortion and shortening of the mesentery If a large number of the glands were destroyed, the passage for the fat might be inadequate

Effect on fat absorption—That tuberculous disease of the mesenteric glands does embarrass the absorption of fat is undoubted Still (1927) gives a good illustration from a specimen which showed the engorgement of the lacteals with caseous material and "perhaps also some fat" The lacteals are seen to be connected with an enlarged gland in the mesentery Only a few of the lacteals are affected If the diseased glands were very numerous and situated near or actually at the root of the mesentery there would be considerable interference with the absorption Talbot (1912) has shown that fat absorption may be prevented by the enlarged glands blocking the lymphatics In our own series there was no gross evidence of serious non absorption of fat apart from the fact that some of the patients on admission were described as being thin or poorly covered Again after operation when it might be expected that the additional fibrosis would constrict the lacteals even more, there was no case with excessive wasting in those examined The operative relief of pressure on the vessels had been adequate

Unusual end results—The development of calcification is not limited to the glands themselves Tubercles on the peritoneal surfaces may become calcified as was found in one of the cases The most likely explanation of this is that they have resulted from healing in an area of generalised tuberculous peritonitis that has become caseous during the acute stage

A female, aged 28, had had an operation 5 years before for a psoas abscess She had passed pus by the bowel 3 years previously She was found at operation to have bilateral tuberculous salpingitis, an irregular calcareous mass at the root of the mesentery an omentum showing many apertures, and in addition *numerous calcareous tuberculous nodules studded all over the abdominal peritoneum* There were also numerous omental bands which were not giving rise to obstruction This patient was untraced after operation

It is interesting in this case to note that there was an appendix abscess which was thought not to be tuberculous, and also the presence of the omental apertures, which may have been caused by the breaking away of the omentum from the caseous areas when they had become calcified

SYMPTOMS AND SIGNS

In a large number of cases, calcareous glands are present in the abdomen without giving rise to any complaint whatever They are discovered by accident in radiological examination for some unrelated condition such as a fracture of the pelvis Such a case is exemplified in Fig 1, taken from a male patient suffering from hæmorrhoids, who had lived to the age of 65 years without having a single abdominal symptom The main symptom that may be ascribed to the presence of calcareous mesenteric glands is generalised abdominal pain later settling in the right lower quadrant of the abdomen It is dragging or colicky, and sometimes radiates to the thigh and back and is accompanied by nausea and occasionally by vomiting In many of the cases the pain is liable to come on in repeated attacks of relatively short duration and is especially worse after exercise and when the patient is fatigued There is usually a tendency to constipation which is worse during the attacks There may be some degree of relationship between the menstrual cycle and the occurrence of the pain Frequently the pain commences in the left abdomen and radiates to the right Some of the patients complain of discomfort some hours after food, some immediately after Backache is also commonly complained of Auchincloss (1930) lays stress on night discomfort after a hard day's exercise and thinks it is due to venous congestion by pressure of the node Aggravation of the symptoms by work or exercise has been very frequently noted in our series of cases. When this is so, rest usually brings relief Often from the history alone a mistaken diagnosis of duodenal ulcer has been made

PHYSICAL SIGNS

Apart from some slight tenderness and hyperæsthesia in the right lower quadrant of the abdomen or the umbilical region, there may be no other physical sign to be made out. There may be some rigidity in the right iliac fossa Infrequently a palpable mass may be felt in some part of the abdomen In this series there was a mass palpable in 11 cases, but of these probably only 5 were due to enlarged glands The situation in all 5 was in the right iliac fossa and one of the masses was tender In another case an indefinite mass was felt in the epigastrium, but it is doubtful whether it was glandular There is usually some distension of the abdomen which may be more marked during attacks of pain Lockwood's sign was present in 33 cases In 29 of them the appendix was found to be bound down to the cæcum by adhesions The constancy of the sign makes it very valuable in the diagnosis of chronic appendicitis An opportunity occurred of testing Lockwood explanation of the mechanism of its production

A patient was admitted suffering from pain, nausea, and vomiting of eight days' duration The diagnosis was one of chronic appendicitis. The sign was positive. At the operation the appendix lay with its tip anchored over the pelvic brim and the lower end of the ileocæcal valve was on the stretch. On pressing the cæcum before the appendix was removed, fine crepitant gurgling occurred and could be repeated as often as desired. After removal of the appendix and freeing of the tension the sign could no longer be elicited.

Golden and Reeves (1929) point out that the leucocyte count is not raised in calcareous gland cases and this would seem a valuable aid in the differential diagnosis from acute and subacute appendicitis.

The *radiological examination* of the abdomen is generally conclusive but it is not uncommon for the reports on gland cases to be misleading. This is often due to the gland overlying the lumbar spine or the iliac bones. If examined carefully and with the eyes on the look-out for the glands they can be easily seen in the film even if they overlie the bodies of the vertebræ (Fig 2). Out of the 201 cases 110 were subjected to X-ray examination of the abdomen. Of these 84 were reported to have calcareous glands present. Thus 26, almost a quarter of the total number examined, were missed on ordinary examination of the films but some of these may have been only caseous. The glands are generally seen round a line extending from the left side of the 2nd lumbar vertebra to the right sacro-iliac joint—i.e. in the line of attachment of the mesentery. They are of irregular shape and have fuzzy outlines. The larger ones are speckled, being apparently composed of many centres of calcification. The typical appearance resembles no other pathological condition (see Fig 3). In our experience ketosis is common. The odour of acetone in the breath or its detection in a sugar-free urine should lead to a radiological examination of the abdomen.

The conditions which might be confused are phleboliths, ureteric stones, enteroliths and opaque bodies in the bowel, stones in a low-lying kidney or gall-bladder and calcareous deposits in an infected kidney. In any case of doubt stereoscopic pictures will often settle the matter or the methods usual in pyelography will help. A good illustration of this is the following:—

A married woman of 29 was sent for consultation on account of a feeling of heaviness and discomfort in the upper abdomen after meals and dating from pregnancy 3 years previously. The patient had had occasional difficulty in urination but no frequency. The urine was found to be normal. X ray examination showed a small calcified gland in the right upper abdominal quadrant but no gall-stone. Visualisation of the renal region and of the gall-bladder shows its relationship to these organs. The latter film shows a small lighter area in the lower third of the gall-bladder which is probably a single cholesterin gall-stone. The patient's symptoms scarcely warranted operation and she was discharged. Unfortunately she left the district and has not been traced.

RESULTS

Of the 106 cases that required operation 22 were untraced. More than half of those traced were examined and the remainder received a questionnaire.

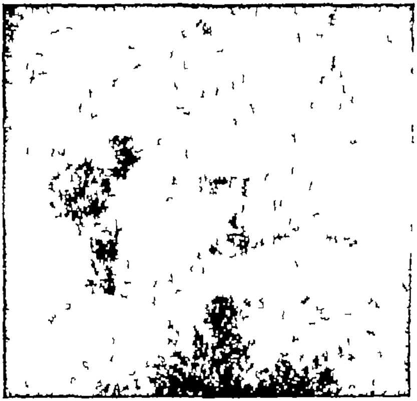

FIG. 1.—Calcified glands in the right iliac fossa, from a man aged 65 who had no symptoms.

Of the 201 cases, 35 required reoperation. 3 patients died shortly after operation, 2 of them having been admitted with acute obstruction and the third being in a very obese female whose wound burst 9 days after the removal of a chronically inflamed appendix and a few calcareous glands and the freeing of some light adhesions. Recent general peritonitis was present, the cause of which was not apparent at the post mortem. The fourth death occurred suddenly two years after post-operative hemiplegia from mitral stenosis. The remaining 163 cases are classed in five groups:—

Group I had 19 cases, discovered at operation performed for conditions in the abdomen other than appendicular disease and bands and included here for the sake of completeness. We have called them "accessory cases." Briefly there were 6 with duodenal ulceration, 2 with gall-bladder disease, 3 had retroversion of the uterus which was treated by operation in 2 cases, 1 had a perforation of the gut by a fish bone and another had a testicular tumour removed. 3 had ovarian cysts, 1 of which was very large. 1 was complicated by bilateral tuberculous salpingitis. In all 17 were traced, 9 being excellent results, 3 good, and 2 poor. One case of carcinoma of the appendix showed a good result three years later. There were 3 deaths.

Group II.—A few cases in which glands were seen at operation but were not removed.

Group III.—Those in which the appendix was found to be subacutely or acutely inflamed, ulcerated or injected.

Group IV.—The largest of all the groups includes those cases where the appendix was found either t [illegible]

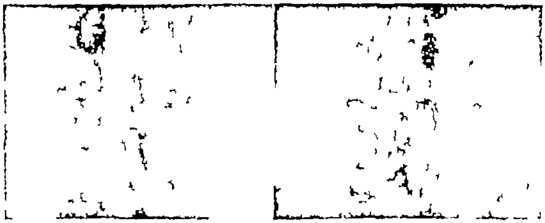

FIG. 2.—Radiograms of a case with calcified mesenteric gland: on the left hidden by the shadow of the middle vertebra; and on the right revealed by displacement of the mesentery.

chronically inflamed or of the atrophic variety, and one case of doubtful tuberculosis of the appendix There was one death

Group V—Where the condition of the appendix was not stated and assumed by us to be normal, or where it was found to be normal

The accompanying Table III summarises the results

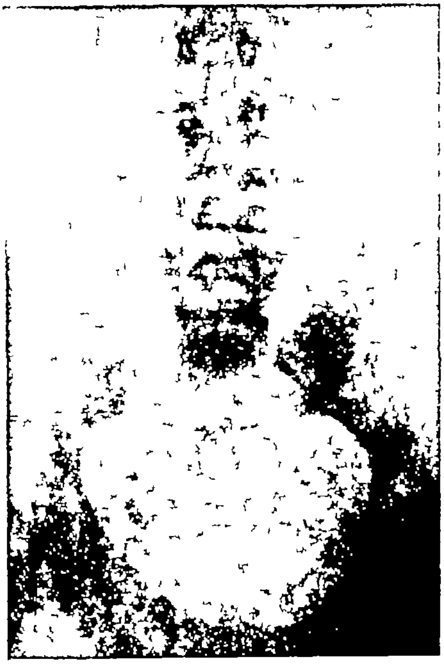

FIG 3—Multiple calcification showing appearance and distribution of the shadows

Reoperation Cases

Of the 201 patients (excluding the 38 caseous cases) who were operated on 35 required more than one operation on the abdomen There were 15 males (of the total 106) and 20 females (of the total 95) Two operations were needed in 21 cases, 11 had three operations, 2 had four operations, and 1 had five operations We traced 31 of these cases, 1 patient had died and 4 remained untraced In their results, 16 were good and 14 unsatisfactory

No surgeon seeks these operations, they are done only from necessity and when the symptoms are considered to be due to a lesion that can be rectified without producing a worse one In the interval, all ordinary care in diet is exercised by the patients and the use of aperients forbidden A filling diet and slow circling exercises three times a day has often given excellent results in those suffering from what might be called "aperientitis" This is certainly true before the first operation in chronic cases

Prophylaxis—It is even more difficult to generalise from these cases than in the cases of calcareous glands Since September, 1929 saline has been left in the abdominal cavity in most cases which were not acute Usually two pints but sometimes more were used the maximum being five pints It is difficult to give any figures to support the impression but it seems that the results after the use of saline had been adopted were much better than before Apart altogether from the improvement in the patient's outlook from the prevention of adhesions there was a very pronounced and almost immediate improvement in the condition of the pulse on the introduction of the fluid

In considering reoperation on adhesion patients it is essential, unless acute symptoms develop, to allow time for the abdominal contents to settle down after the trauma of the last operation The ward sister states that the immediate post-operative condition is always more troublesome in these cases than in many so called larger operations Even in patients who had only one operation, we were struck by the numbers who had a fair amount of abdominal discomfort up to six months after operation and even longer In many cases adhesions disappear altogether if left for a long time If the patient's life is a misery at the end of two years operation should be undertaken

Tuberculosis of the Appendix

During the period under consideration 106 appendices were submitted to microscopical examination for evidence of tuberculosis Of these, 93 were from cases of caseous and calcareous mesenteric glands and the other 13 were included because of some irregular thickening or sclerosis observed at operation, 3 only showed evidence of tuberculous disease In 1 of the 93 gland cases a single minute area alone showed signs of actual tubercle, but 8 showed prominent and active lymphoid deposits in the mucosa

Among the 13 cases included—no diseased glands being present—because of irregular thickening or sclerosis, were 2 of undoubted tuberculosis In both cases the disease was limited to the appendix itself and *in both the mesenteric glands were unaffected*, which shows that the statement made by Sir William Willcox (1934) may not always hold "I would remind you that one sometimes meets with a tubercular appendix That may possibly be diagnosed by the history of the case but at operation it is diagnosed by the presence of tubercular glands"

TABLE III

Operative Results

Totals	144	22	109	17	6	8	4	166

Conclusions

(1) The caseous stage of tuberculous mesenteric glands is the dangerous one from the point of view of the spread of the disease, the complications, and the mortality (2) Bursting of a caseous mesenteric gland is probably a fairly frequent event and results in various degrees of tuberculous peritonitis (3) Caseous mesenteric glands are a common cause of pathological conditions leading to intestinal obstruction (4) There is apparently a relationship between the caseation and the inflammatory conditions of the appendix Caseous glands should be removed when found at operation and appendicectomy carried out as a routine (5) Adhesions and bands of various kinds often result from the healing of subacute tuberculous peritonitis (6) Calcareous mesenteric glands alone frequently give rise to symptoms and

require to be removed (7) Appendicectomy alone is sometimes done in acute or subacute cases when tuberculous glands are the cause of the symptoms (8) Abdominal tuberculosis in young adults according to other workers appears to be more severe than that found in a ward for general surgical cases (9) There appears to be very little liability to the stirring up of a tuberculous lesion when glands are removed even if they are caseous (10) The administration of intraperitoneal saline at the end of the operation tends to prevent adhesions. (11) Reoperation should not be undertaken if it can be avoided before two years have elapsed (12) *Progressive calcification in mesenteric glands* as shown by repeated X ray examination can be a guide in prognosis (13) Tuberculosis of the mesenteric glands tends in the main to natural cure

We are indebted to the honorary staff of the electrical department of the Aberdeen Royal Infirmary for the loan of many radiograms; to the late Dr G M Duncan for the examination of the pathological material and for his advice on numerous occasions to Dr G S Banks for his reports on the patients admitted to the Municipal Hospital; to Prof Shennan and his assistants in the pathological department of the University of Aberdeen for the reports of the post mortem examinations and to the ward sister and the members of the nursing staff of the Aberdeen Royal Infirmary for their help on many occasions

INTRADERMAL TESTS FOR SUSCEPTIBILITY TO WHOOPING-COUGH

By Brian O'Brien M.B N U I

LATE SENIOR ASSISTANT MEDICAL OFFICER TO THE CORK STREET HOSPITAL, DUBLIN

In the sphere of communicable disease the prevention and control of whooping-cough is now regarded as one of the most serious problems confronting public health authorities The disease is responsible for 2000–3000 deaths annually in England and Wales and as many as 40 000 cases of the disease are said to occur every year in London alone These figures do not reflect the vast amount of physical and nervous suffering the loss of school attendance and the risk of impaired health and lowered resistance to tuberculosis that those who survive an attack of whooping cough are apt to incur

It must be admitted that in the past efforts to control this disease—by school notification isolation of sufferers exclusion of contacts and more recently administration of convalescent serum—have not been attended by any substantial measure of success Within the last few years however the suggestion that methods of specific immunisation might be effectively employed in whooping-cough prophylaxis has brought renewed hope and in spite of recent efforts to implicate filtrable viruses in the causation of the disease Sauer's claim that he can immunise children against pertussis by means of a specially prepared vaccine of the Bordet-Gengou bacillus continues to command serious attention

THE TEST

A little more than a year ago Paterson Bailey and Waller (1935), while confirming in the main Sauer's results attempted to devise a skin test of susceptibility to whooping cough using as their antigen Sauer's vaccine The present investigation prompted by this latter work is an effort to estimate the reliability of this intradermal test as an index of susceptibility So far I have made no attempt to assess the practicability of active immunisation by Sauer's technique

The test is based on the skin reaction to an intradermal injection of Sauer's vaccine (1933) which is made from 5–7 strongly hæmolytic strains of *Hæmophilus pertussis* (*B pertussis* of Bordet and Gengou) isolated from early cases of whooping cough by the cough plate method

The bacilli are grown for 48 hours in an incubator on the cherry-red Bordet medium made with freshly defibrinated human (placental) blood. The bacilli are scraped off and suspended in 0 5 per cent phenolised physiological salt solution and left to stand in a refrigerator for one week. Sterility is ensured by culture on three successive days The concentrated vaccine is then diluted until 1 c cm contains approximately ten billion bacilli and it is stored in a refrigerator until required for use

Technique—Into the forearm 0·1 c cm. of Sauer's vaccine is injected intradermally so as to produce a raised weal. The skin reaction at first was read at 24 and 48 hours after injection but subsequently the 48-hour reading was discontinued as it was found that strongly positive reactions at 24 hours had very often so faded as to make an accurate reading impossible at 48 hours. Careful observation showed that in all cases where a positive skin reaction developed it did so within 12 hours of injection It was further noticed that strongly positive reactions at 12 hours were often much less definite 12 hours later In the latter half of this investigation accordingly the reactions were read at 12 hours and again at 24 hours after injection

Reaction.—A positive reaction varied widely from a mild hyperæmia of the skin at the site of injection circular in form and about 10 mm in diameter to an intense hyperæmia at least 30 × 20 mm. in extent with raised edges and some induration. This latter type of reaction faded from red through pink to brown and had usually disappeared in 72 hours without leaving any residual staining

At first the interpretation of the milder reactions gave rise to considerable difficulty and until 100 cases had been tested there was a tendency to regard as positive reactions which with further experience one learned to classify as merely the response of the skin to the trauma of the needle In particular with the sensitive skins of infants up to 18 months of age this traumatic factor was apt to show itself and resulted in a certain number of reactions being interpreted as positive in cases where there was no doubt about the absence of any history of whooping cough This possible fallacy (referred to again later) must be borne in mind in considering the results of the present investigation Although the difficulty of interpretation would appear to lessen the value of the test for routine diagnostic purposes it should be made clear that with further experience it was found possible to differentiate between purely traumatic responses and the true positive reaction in every case

A positive reaction is here taken as connoting immunity to pertussis, although it is realised that objections might be raised to this on the ground that the skin reaction would be given by persons who were sensitive to other members of the group—e g, *Hæmophilus influenzæ*—while non immune to the Bordet Gengou bacillus Again, it might be urged, on the analogy of the Mantoux test in relation to tuberculosis, that a positive skin reaction indicated merely previous experience of the bacterial antigen short of immunity to clinical pertussis But, it is submitted that the antigen used in this investigation —viz, a specially prepared vaccine containing the whole Bordet Gengou bacillus—places the test on a different plane to the Mantoux, to group intradermal tests, and to the test recently described by Siebler and Okrent (1934)

RESULTS

The test was originally performed on children and adults irrespective of age but was subsequently restricted to children under 10 years of age owing to the difficulty of obtaining a reliable history of previous infection in adults This difficulty existed also to a less extent in children, but the history of previous infection can be personally vouched for in all cases included in the present investigation The Table gives the results of the investigation The fact that 40 cases gave immune reactions in spite of no history of clinical whooping cough is at first sight rather disconcerting, but when allowance is made for the development of immunity in a highly urbanised population because of repeated small doses of *H pertussis* causing subclinical varieties of the disease, this discrepancy becomes more understandable Latent epidemics must be fairly active in a city with housing conditions like Dublin Furthermore it is generally agreed that not more than 60 per cent of all children in a community exhibit frank manifestations of whooping cough at some time or other (Leslie and Gardner 1931) While the escape of the remaining 40 per cent may be due to absence of exposure to infection, an inherent resistance to disease is admitted by all epidemiologists An instance of this noticed in the present investigation was in the case of two brothers A and B, aged 4 and 6 who both showed strongly immune reactions although only A had suffered from whooping cough

Results of Skin Test for Whooping cough (371 *Cases*)

Past history	Reactions			
	Positive		Negative	
No whooping-cough	40	29 %	208	90 %
Whooping-cough	99	71 %	24	10 %
Total	139	100 %	232	100 %

During the investigation certain interesting features emerged

(1) Four cases of whooping-cough seen late in the spasmodic stage all showed strongly immune reactions

(2) A case of scarlet fever who had been in contact with whooping-cough was found on routine testing to show a non immune reaction In due course he developed whooping-cough and five weeks after the first test was retested when he gave an immune reaction

(3) There were 9 cases in close contact with a case of whooping cough but with immune reactions, who never developed the disease although only 2 of these had a definite history of a former attack.

(4) A child suspected of developing whooping-cough gave a negative (non immune) reaction Under observation the suspicion was dismissed on clinical grounds Repeated tests with Sauer's vaccine gave a persistently negative (non immune) response

(5) Although active immunisation was not included in the scope of this preliminary investigation three children with non immune reactions were given a course of immunising injections with Sauer's vaccine, receiving three weekly subcutaneous doses of 1 c cm, 1 5 c cm, and 1 5 c cm into each arm, making a total of 8 c cm for each case Tested one week after the third injection all had strongly immune reactions

CONCLUSIONS

A series of 371 cases were examined for susceptibility to whooping cough by an intradermal test, using Sauer's vaccine as an antigen the results were compared with the history of previous infection

The results of skin testing show a high measure of correlation in those patients having non immune reactions, 90 per cent of whom gave no previous history of whooping cough

A slighter measure of agreement between the result of the test and the previous history was shown in the case of those giving immune reactions, 71 per cent of whom were known to have had an attack of whooping cough. It is certain that some at least of these reactions were incorrectly read as positive (or immune) at the commencement of the investigation

Certain incidents—the insusceptibility of positively reacting (immune) patients after exposure to infection, and the change of the reaction from negative to positive after an attack of whooping cough—support the view that the test is, within limits, a reliable index of susceptibility to *H pertussis* infection

I wish to express my thanks to Dr C J McSweeney, medical superintendent of the Cork-street Hospital, at whose suggestion this work was undertaken, for help and encouragement during the investigation

THE DIAGNOSIS OF WHOOPING-COUGH

THE COMPLEMENT FIXATION AND INTRADERMAL TESTS

By J P J Paton, M B Glasg
RESIDENT MEDICAL OFFICER TO THE BELVIDERE ISOLATION HOSPITAL, GLASGOW

The landmarks in the laboratory diagnosis of whooping cough are briefly the following —

In 1906 *Bacillus pertussis* was first described by Bordet and Gengou as the causal organism of whooping cough. They also found (1907) that the serum of patients convalescing from whooping cough had the property of deviating complement when *B pertussis* was used as antigen. Leucocytosis in whooping cough had been previously described by Fröhlich (1897), while later investigators found that a relative lymphocytosis was the outstanding feature in the hæmatological picture The bacteriological diagnosis of whooping cough by the "cough plate method" was introduced by Chievitz and Meyer (1916), and has since been used extensively in Denmark and other countries with considerable success in the early diagnosis of the infection In 1931 Leslie and Gardner dealing with the antigenic structure of the organism, clarified the confusion on the subject by describing four antigenic phases of *B pertussis* Phase I being the most toxic and the best antigen for vaccines with Phase II it corresponded with the smooth state Phases III and IV with the rough state of other organisms

An intradermal test for the diagnosis of whooping cough has been used by several investigators with varying results. Siebler and Okrent (1934) came to the conclusion that children with a previous history of whooping-cough usually gave negative skin tests the converse being also true—that children with no previous history of whooping cough usually gave a positive skin reaction The vaccine used by these investigators was one prepared in a similar manner to that used by Sauer (1933) On the other hand Paterson Bailey and Waller (1935), also using Sauer's vaccine found that children with a previous history of whooping-cough usually gave a positive skin reaction whilst children with no previous history of whooping-cough gave a negative skin reaction In a subsequent letter in the same year Paterson (1935) stated that the results obtained varied with the batch of vaccine used

Methods and Material

The material used in the present investigation consisted of patients suffering from whooping-cough with or without complications who had been admitted to the wards of Belvidere Hospital during the epidemic of whooping-cough in Glasgow in the winter of 1934–35 ; children convalescing from broncho pneumonia during the following winter were used as controls

TECHNIQUE OF THE COMPLEMENT FIXATION TEST

The antigen used in the majority of the complement fixation tests was the St Mary's Hospital prophylactic A vaccine issued by Parke Davis and Co in a concentration of 4000 million whole *B pertussis* per c cm This vaccine is stated to be prepared from smooth strains of *B pertussis* It was found that a dilution of 1 : 5 of this antigen had practically no anticomplementary effect

TABLE I—*Complement-fixation Tests*

M H D of complement	2	3	5	Serum control 2	Result
Hæmolysis	c	c	c	c	Negative
	m tr	c	c	c	Doubtful positive
	tr	a c	c	c	Weak positive
	0	tr	c	c	Positive
	0	0	c	c	Positive.

M H D = minimum hæmolytic dose 0 = no hæmolysis tr = trace of hæmolysis m tr = marked trace ; a c = almost complete hæmolysis c = complete hæmolysis

In the test proper 0 25 c cm. of the diluted antigen was added to each of 4 test-tubes To each of these and to a fifth serum control tube containing 0 25 c cm of normal saline the patient's serum was added in amounts which varied from 0 05 c.cm in the first series of cases to 0·2 c.cm of serum from the later batches of sera, this latter amount of sera having been considered to be the optimum amount of serum for the test The complement dose of fresh guinea pig's serum was estimated for 0·5 c cm of sensitised sheep cells (3 per cent) and 2, 3, 5 and 7 doses of complement were added to tubes 1 2 3 and 4 and two doses to the fifth serum control tube In the later complement fixation tests the fourth test tube containing 7 doses of complement was omitted. The test tubes and their contents were incubated for 1½ hours at 37 C after which 0 25 c cm of sensitised sheep cells (3 per cent) was added, incubation being carried out for a further hour at 37° C. In each batch of complement fixation tests serum and antigen controls were put up and a positive human or rabbit serum was included in the tests.

Table I indicates how the readings were recorded In the analysis of results doubtful positive reactions were recorded as negative

In order to test the antigenic efficacy of the various vaccines a rabbit was given intravenous injections of the St Mary's vaccine and complement fixation tests were done in the usual way using St Mary's vaccine Madsen's Danish vaccine and Sauer's vaccine All the vaccines fixed complement satisfactorily best results being given with the Sauer vaccine

TECHNIQUE OF THE INTRADERMAL TEST

The following vaccines were used for the skin test

(1) Sauer's pertussis vaccine containing 10 000 million organisms per c cm

(2) Whooping-cough dissolved vaccine containing the dissolved constituents of 4000 million or 8000 million organisms per c.cm. prepared by the Glaxo Laboratories Ltd

(3) Whooping-cough vaccine (prophylactic A) containing 4000 million organisms per c.cm. prepared by the Inoculation Department, St Mary's Hospital (issued by Parke Davis and Co)

(4) Kreuger's bacterial antigen prepared by mechanical disruption of masses of *B pertussis* 1 c cm. of the undenatured antigen being roughly equivalent to 10 billion bacilli.

All of these vaccines consist of whooping-cough bacilli alone either in the intact state (e g Sauer's and St Mary's vaccine), mechanically disrupted (e g Kreuger's vaccine) or chemically dissolved (e g Glaxo vaccine) None of the vaccines used were in a dilution lower than 4000 million organisms per c cm

In each case 0 1 c cm of the vaccine was injected intradermally on the flexor aspect of the forearm the proper antigen control being used for each different type of vaccine except in one case where Kreuger's vaccine was used without a control. The readings were taken when the reactions were at their height usually 18 hours after the test had been done Later readings were also taken but these were invariably found to be less intense than the 18 hour readings

A skin reaction was considered positive when the area of redness was 1 cm or more in its longest diameter the control test being negative There is usually an area of induration which may or may not be more than 1 cm across in each skin test if it is positive ; this indurated area when present is both visible and palpable

Results

THE COMPLEMENT FIXATION TEST

The results of the *complement fixation tests* will be considered in two groups (1) *cases not treated therapeutically with B pertussis vaccine and* (2) *cases so treated* In each of these groups a *special analysis* will be made of cases with negative reactions in an attempt to find out the causes of the negative tests There is a third group of control cases

Group 1 non vaccine treated—There were 58 *patients in this group of whom 44 or* 75·8 per cent gave positive complement fixation tests

The average duration of infection from the onset of the illness until the blood had been withdrawn was 4 [illegible] days Patients from whom blood had been withdrawn on or before the twenty first day of illness numbered 21 of whom 15 or 71 42 per cent gave positive complement fixation reactions. The duration of illness from the onset until blood was withdrawn in the remaining 6 cases with negative complement-fixation tests was respectively 6, 9 10, 18, 19, and 21 days There were 37 patients who had blood taken off after the third week of illness, and of these 29, or 78 40 per cent, gave positive complement fixation tests An analysis of the reactions according to age groups in these 58 cases suggests that the antibody response is less active in the younger children, so that negative tests are most likely to occur in the younger age groups (see Table II)

TABLE II—*Variation with Age*

Age in years	Number of cases	Negative	
		Number	Per cent
0–2	15	5	33 3
2–5	34	9	26 4
5 and over	9	0	0

When the 14 cases with the negative complement fixation reactions were further analysed various factors possibly responsible for a negative reaction were elicited These are as follows —

1 Extreme youth 4 cases were less than a year old when blood was withdrawn

2 A short duration of illness before the blood was withdrawn 6 cases had blood withdrawn 3 weeks or less from the onset of the disease

3 Anticomplementary sera 3 cases were labelled as having negative complement fixation tests because their sera were anticomplementary

4 A severe form of whooping-cough 2 cases had severe whooping cough when the blood was withdrawn

5 The presence of acute complications 2 cases had broncho pneumonia when blood was withdrawn

6 In addition, in 6 cases, less than what was later regarded as the optimal amounts of antigen or serum or both was used, while 6 of the 14 cases were recorded as "doubtful positives"

It may be noted that in the above analysis of the various factors tending to produce a negative result each case may have been influenced by one or more factors It is of interest to note that in two cases the complement fixation tests which were at first negative became positive when blood was withdrawn for a second test, and in another two cases the complement fixation test when repeated showed an increase in the positivity of the test (Table III)

TABLE III—*Changes in Complement fixation Test*

Case	Age	Day of illness when blood was withdrawn	Result
A	3½ years	11 38 71	Negative Doubtful positive Positive
B	7 months	6 20	Negative Weak positive
C	4 years	45 73	Weak positive Positive
D	4½	14 33	Weak positive Positive

Group 2 vaccine treated—Of 43 cases treated with the smooth form of pertussis vaccine, 36, or 83 7 per cent, gave positive complement fixation reactions

The average duration of the illness from the onset until the blood was withdrawn was 55 8 days The average amount of vaccine given to an individual patient up to the time when the blood was withdrawn was 14 75 c cm of a vaccine containing 4000 million smooth strain whooping cough bacilli per c cm In this group there were only 4 cases from whom blood had been withdrawn on or before the twenty first day of illness Each of these 4 cases gave positive complement fixation reactions. Of the 39 cases who had blood taken off after the third week of illness 32 gave positive complement-fixation reactions (82 05 per cent)

Again as in Group 1 it is interesting to note the number of cases with negative complement fixation reactions in the various age groups (Table IV)

TABLE IV—*Variation with Age*

Age in years	Number of cases	Negative	
		Number	Per cent
0–2	22	5	22 7
2–5	16	2	12 5
5 and over	5	0	0

An analysis of the 7 cases with negative complement-fixation tests reveals similar factors to those acting in Group 1, and again the result of each complement fixation test may have been influenced by one or more factors

1 Extreme youth 4 children were less than a year old when the blood was withdrawn

2 Anticomplementary sera The sera was anticomplementary in 3 cases, each result being labelled negative

3 A severe form of whooping cough 1 case had severe whooping cough when the blood was withdrawn

4 The presence of acute complications 1 case had broncho pneumonia when blood was withdrawn

5 In 2 cases less than the optimum amounts of antigen or sera or both were used, and there were 2 doubtful positives amongst the 7 cases recorded as having negative complement fixation reactions

Control series—In a control group of 37 children, aged 0–5 years, convalescing from broncho pneumonia and with no previous history of whooping cough 36 had negative complement fixation reactions and 1 gave a "doubtful positive" reaction

THE INTRADERMAL TEST

In this section the object was to investigate the possible value of the skin test in the diagnosis of whooping cough, using the complement fixation test as a control The blood for the complement-fixation test was withdrawn in each case before the skin test was done The cases have been divided into two groups Group A consisted of 43 patients untreated by vaccines, most of whom were under five These patients had been admitted to the wards with the diagnosis of whooping cough with or without complications Group B was composed of 37 patients, aged up to 5, who were convalescing from broncho pneumonia and had no previous history of whooping cough This group has thus been used as a control to Group A of this series, as well as acting as control material for the complement fixation test

Group A—Of the 43 cases 25 were skin tested with Sauer's vaccine, 14 were skin tested with St Mary's vaccine 3 were tested with Glaxo vaccine composed of 8000 million organisms per c cm, and one was skin tested with Kreuger's vaccine Out of the 43 cases 31 gave positive complement fixation reactions and, of these 31 cases 21 gave positive skin tests Of the 12 cases with negative complement-fixation reactions 9 gave positive skin tests Altogether 30 out of the 43 cases (69 7 per cent) gave positive intradermal tests

Group B—The antigens used for the skin tests in this group were Sauer's vaccine and Glaxo vaccine containing the constituents of 8000 million whooping-cough bacilli per c cm Each case was tested at the same time with the two vaccines

Of the 37 cases, 36 gave negative complement-fixation reactions and 1 case had a "doubtful" reaction. In the skin tests 31 cases of the 36 were positive with both Sauer's and Glaxo vaccine Amongst the remaining 5 cases, 3 gave negative skin tests with both antigens, 1 gave a negative skin test with the Sauer antigen, and a positive skin test with the Glaxo antigen whilst the other gave a positive skin test with Sauer's vaccine and a negative skin test with the Glaxo vaccine The case with the doubtful positive complement-fixation reaction gave a positive skin test with both the Sauer and the Glaxo vaccine

Summary

The complement fixation test is of value in confirming the clinical diagnosis of whooping-cough In *atypical cases the test may by itself establish the* diagnosis of pertussis by conversion from a negative to a positive reaction during the course of the illness.

Although the majority of the patients in this series were admitted in the later stages of the infection there is evidence from the numbers admitted in the first three weeks of the disease that the complement fixation test becomes positive early in the infection in a high proportion of cases

Negative results were most commonly obtained in very young children in whom there seems to be a poor antibody response Other apparent causes of a negative reaction were short duration of the disease very severe infection or presence of complications and anticomplementary sera

The intradermal test failed to give specific results A high percentage of patients with whooping-cough gave positive *reactions but so also did a group of* control patients with no history of whooping cough There was no correlation between the intradermal test and the complement-fixation reaction

This work was commenced in Belvidere Hospital Glasgow in December 1934 with the kind permission of Dr A S M. Macgregor medical officer of health for Glasgow and Dr Thomas Archibald medical superintendent The complement-fixation tests were carried out in the bacteriological department of the Royal Infirmary Glasgow under the personal supervision of Dr Robert Cruickshank bacteriologist to the Royal Infirmary to whom I am indebted for animal inoculations and for revision of the text

GREENOCK ROYAL INFIRMARY —At the annual New Year's Day meeting of subscribers to Greenock Royal Infirmary it was announced that the directors had adopted a scheme for extending the Larkfield Hospital to provide 50-60 additional beds The chairman Mr D N Ferguson said the proposed extension would do away with the waiting list though they were more fortunate than many hospitals in having only 11 on their list Various substantial legacies and gifts had been received by the hospital during the year and the income from all sources had increased. He hoped that the final statement for the year would show that the debit balance that had accumulated during the years of trade depression had almost gone

NÆVOCARCINOMA OF THE SKIN AND MUCOUS MEMBRANES

By I G Williams M.B Lond
F R C S Eng D.M.R.E
ASSISTANT RADIOTHERAPIST TO THE MIDDLESEX HOSPITAL AND
L C Martin M.B Camb M.R C.P Lond.
ASSISTANT PATHOLOGIST TO THE BLAND-SUTTON INSTITUTE, MIDDLESEX HOSPITAL

NÆVOCARCINOMATA have for many years interested pathologists because of their colour and physicians because of their generally fatal result The many theories put forward about the origin of their pigment and the derivation of their characteristic cells have led to a confused nomenclature but clinicians are all agreed on their extreme malignancy

An analysis of 25 cases admitted to the Middlesex *Hospital during the years* 1928–35 *together* with some cases of benign melanomata, has been made in order to study the histology to correlate the histological and clinical types with prognosis and to emphasise the clinical features In the discussion on treatment more recent cases have been included and no attempt has been made to give a statistical survey

The term nævocarcinoma was introduced by Unna to cover the group of malignant tumours previously known as the melanoblastomata Controversy has raged as to whether these tumours are carcinomata or sarcomata as they may consist of cells whose appearance suggests epithelial or connective tissue origin (Unna 1893 Ewing 1930 Dawson 1925 and Masson 1926) and some authorities recognise two types the melanocarcinoma and the melanosarcoma. Both are usually characterised by the presence of pigment but the problem is complicated by the occurrence of tumours histologically identical but without pigment Cases have been noted where the primary growth is pigmented whilst the secondary deposit is not or where the primary tumour is non pigmented whilst the secondary deposit is deeply coloured

BENIGN PIGMENTED TUMOURS

Benign pigmented tumours are extremely common Pack quoted by Adair (1936) in a careful clinical investigation found that every individual has at least 20 pigmented spots on his person. These spots are important for two reasons—they may cause disfigurement or become malignant

Disfigurement —Fifty per cent of these tumours occur on exposed surfaces of the body—i e face neck, and arms—and the patient seeks advice for cosmetic reasons The safest and best procedure in these cases is a thorough and clean excision with a scalpel as there is abundant proof that trauma in the form of electrodesiccation and burning with carbon dioxide snow may excite a malignant change They are not radiosensitive although a hairy mole may be depilated

Malignant change —Twenty per cent. of our cases of nævocarcinomata arose as a malignant change in a previously benign melanoma As Sampson Handley has pointed out the chances of a benign melanoma becoming malignant however must be very small, at least some thousands to one The points of practical importance are: (1) Which type is liable to become malignant? (2) The factors exciting malignant change (3) The clinical evidence of malignant transformation, since histologically it may be very difficult to be certain whether a mole is benign or malignant

Types —In our cases the following clinical types occurred —

1 A diffuse flat pigmented type
2 A raised hard nodular type, often papillary
3 A soft raised nodular type
4 A hairy circumscribed type

Site —The majority of these apparently benign melanomata occurred in the upper half of the body, their sites being cheek (2 cases), cervico dorsal region (1 case), upper abdomen (1 case), and sole of the foot (1 case) Of these 5 cases one, the hard raised nodular type with a papillary surface, had progressed to a squamous celled carcinoma In this type the cells are differentiated along the line of squamous epithelium and are only secondarily pigmented There were 3 cases of the soft raised type that became nævocarcinomata, being raised they were subjected to trauma and exposed to constant friction which was probably a potent factor in exciting malignant change The fifth case was of the diffuse flat type on the upper abdomen, was subjected to friction by tight clothing, and was also a nævocarcinoma

Signs of malignant change presented themselves in one of the following forms —

1 Increase in size of the original tumour
2 Ulceration
3 Hæmorrhage
4 Appearance of nodules in the skin around the original tumour
5 Enlargement of lymph glands without change in the original tumour

ACQUIRED NÆVOCARCINOMATA

Out of an average of 800 cases of malignant disease seen annually at the Middlesex Hospital during the years 1930 to 1935, there were about 6 cases of nævocarcinoma a year Their ages varied from 19 to 81, the greatest incidence being the sixth to seventh decades Both sexes were equally affected Clinically demonstrable secondary deposits were present in 60 per cent of the cases when they first sought advice, and one case developed inoperable glands while awaiting admission to hospital. In one case wide spread metastases made themselves apparent clinically during the 14 days after the surgical removal of the primary growth

Clinical types —

1 Nodular, papillary, or warty
2 Pedunculated
3 Associated with neurofibromatosis
4 Ulcerated
5 Subcutaneous nodular
6 Glandular enlargement, no primary lesion found

Some cases are difficult to assess as truly acquired, since the congenital type may be subcutaneous and latent

Sites —In our series the acquired nævocarcinomata occurred at random on skin and mucous membranes face (4 cases), ear (2), palate (1), nasal mucous membrane (1), chest (1), abdomen (2), arm (5), thigh (3), and lower limbs (6) No case of nævo carcinoma occurred in normally pigmented areas, such as the axilla, areola of the nipple, linea nigra, or anal region

Features —Of the 25 cases, 8 showed non pigmented tumours The ulcerated type commenced as a raised nodule the centre of which broke down to leave an indurated edge In many, owing to rapid growth, the edge was softer than in the squamous epitheliomata Some of the non pigmented clinical types had a slight black rim at the edge of the ulcer which gave the clue to their nature In some of the other cases there was no central degeneration, a soft, raised, bleeding tumour being exposed when dressings were removed There were 2 cases in the series associated with multiple nodules on the abdomen and thighs, which followed the course of subcutaneous nerves and were diagnosed clinically as multiple neuro fibromata One of these cases had a nodule on the thigh which was cystic and pigmented. There was only one case in which histological examination of an enlarged gland revealed nævocarcinoma and where a primary could not be found

Histology —Material consisting of skin and lymphatic glands was examined from 23 cases of nævocarcinoma Three types of tumour cell were distinguished —

1 The "squamous" type is named because of its superficial resemblance to the cells of squamous epithelium The cell is irregular or polygonal in shape with an eosinophilic cytoplasm and nuclei variable in shape and staining intensity, showing mitotic figures

2 The "spheroidal" type is so named because it resembles cells occurring in spheroidal-celled carcinoma These cells consist almost entirely of large, pale staining reticulated nuclei, often showing mitosis, and a minimum of cytoplasm

3 The "spindle" type resembles sarcoma cells The nuclei are irregular in shape and size with mitoses and little cytoplasm

Two distinctive arrangements of tumour cell were encountered

The papillary type, in which the tumour cells lay in loose papillary formation, in relation to a connective tissue stroma which appeared to be part of the growth, as distinct from connective tissue of the invaded tissue This arrangement was largely favoured by the "squamous" type of cell (Fig 1A)

Closely packed masses of tumour cells with little or no stroma, a formation largely adopted by the "spheroidal" type of cell (Fig 1B)

Certain growths showed no definite arrangement and were in the nature of a diffuse infiltration Where there was a definite arrangement in the primary growth it persisted in the lymphatic gland metastases in some cases The following combinations of cell type and arrangement were met with —

1 Papillary arrangement of squamous type of cell 13 cases
2 Masses of "spheroidal" type of cell 5 cases
3 Masses of "squamous" type of cell 3 cases
4 Masses of "spindle" type of cell 2 cases

Pigmentation —In the 23 cases 11 tumours were pigmented, and in one case pigment was present in a lymphatic gland metastasis from an apparently non-pigmented primary The pigment appeared to be deposited in the tumour cells themselves, in the "squamous" and the "spindle' cell types of growths

Benign pigmented moles —Examination of sections of benign pigmented moles led to the following conclusions (1) All three types of cell "squamous," "spheroidal," and "spindle" occurring in nævocarcinoma could be recognised (2) There was no histological difference between cells of the same type in benign and malignant growths, barring the greater frequency of mitosis in the latter (3) The majority of benign growths showed a mixture of squamous cells in papillary arrangement in the superficial layers with masses of 'spheroidal" cells in the deeper layers

Malignant change in congenital moles—In 4 of our 25 cases there had been sudden rapid growth of pigmented moles which had been present for 20, 25 34 and 40 years a history of trauma being definite in one case No histological difference could be detected between these growths and those apparently arising de novo (Fig 2)

Biopsy in doubtful cases—Darier and Ravaut (Darier 1936) state that a biopsy in a doubtful case should never be performed as the histological picture is difficult to interpret and the trauma may be a factor in precipitating a malignant change in the tumour Such cases should be treated as nævocarcinomata

TREATMENT

Surgery—The majority of primary tumours were excised with the scalpel or diathermy knife In all cases where possible whether there were palpable glands or not the regional lymphatic glands connected with the primary tumour were excised All tumours in which a local excision was done recurred either locally or in the neighbouring skin and necessitated a second operation In some cases the primary *tumour secondary metastases and the connecting* fascial lymphatic channels were excised In one case of primary nævocarcinoma of the foot amputation through the lower third of the femur was performed, together with a wide radical dissection of the inguinal glands being the only means of ensuring complete removal The glands were not invaded and this case is still alive without evidence of recurrence three years later In spite of wide excision some cases advanced rapidly

In a recent case a small congenital mole on the ear which suddenly increased in size was removed locally and proved to be a nævocarcinoma on section The patient was admitted to hospital immediately and a wide excision of the ear was done together with an extensive block dissection of the cervical glands 6 weeks later a recurrence developed in the lymphatic glands of the pre-auricular region and in a gland low in the posterior angle of the posterior cervical triangle

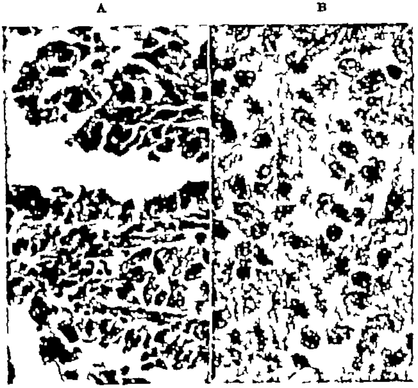

FIG 1.—(A) Papillary type of nævocarcinoma with "squamous" cells (B) Closely packed "spheroidal" type of cells

Radiotherapy—Isolated instances are recorded in the literature of successful treatment of nævocarcinomata by radiotherapy (Holfelder 1929 Pack 1928 Anderson 1935 McEuen 1930) The French school of dermatologists however state that the tumour is so radioresistant that radiotherapy is contra indicated Even surgical excision is condemned as being insufficient and as leading to a false sense of security and they advise treatment by diathermy coagulation We have found some cases to be sensitive to gamma rays of radium and to X rays. The methods of application depended upon the site of the primary tumour

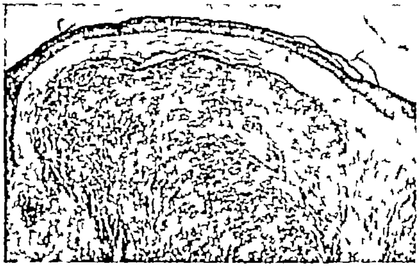

FIG 2.—Showing squamous cells in papillary arrangement in superficial layers and spheroidal cells in the deeper layers.

CASE 1—Female aged 35 with 6 months history of slightly pigmented raised tumour on dorsal surface of the big toe with enlarged glands in the groin The primary was treated by a surface application of radium on a Nidrose applicator a dose of 6000 *r* units being given in 10 days The reaction proceeded to a moist desquamation with rapid healing and disappearance of the original tumour The inguinal glands were excised and a post operative course of deep X ray therapy given There was no recurrence to date 9 months later

CASE 2.—Male, aged 26 with 9 months history of an ulcerated growth fixed to the hard palate and alveolus Treated by surface application of radium on a dental applicator receiving a dose of 7000 *r* in 10 days, together with 118 hours by a 1 gramme unit to the neck in 32 days The primary lesion healed satisfactorily and there is no recurrence to date 8 months later

CASE 3—Male aged 63 with 3 months history of an ulcer on the thigh with a recent lump in the groin. The primary was treated by deep X ray therapy receiving a dose of 8000 *r* in 6 weeks 100 kv 6 mA; distance 40 cm The primary lesion healed rapidly while undergoing treatment but recurred within three months on the margin of X ray pigmentation

Of other cases treated 1 case with fixed inguinal glands became operable 1 case with a nævocarcinoma of the nasal mucous membrane responded well to teleradium therapy and 1 case with a large recurrence in the dorsal region responded well to surface radium treatment; the tumour became smaller and flatter and ultimately disappeared Many cases are definitely radioresistant No criterion of radio sensitivity has been found by histological examinations except that the non pigmented tumours appear to be more sensitive than the pigmented If pigmentation is an index of cell activity and therefore differentiation it would agree with the suggestion that non pigmented tumours being undifferentiated are more malignant (see prognosis) and possibly more radiosensitive

PROGNOSIS

The prognosis of nævocarcinoma is generally considered to be very poor All our five undoubted congenital cases are alive and well without recurrence, 1 for 5 years, 3 for 2 years and 1 for 1 year after treatment

Of the 20 "acquired cases," 15 are dead, 1, 7 years after treatment, from senility, 1 after Cæsarean section for spinal metastases 2 months after excision of the nævocarcinoma, 8 cases in the first 2 years after the onset of the illness, and 4 of these in the first year, while the remainder died within 5 years All these cases received treatment in the form of surgery or radiotherapy, and in one case alone was the disease so advanced that palliative surgery only was attempted In 3 cases there were local recurrences in the first year, and in 2 cases in the second year after treatment In 2 of these cases the recurrence was re excised more radically but recurred again within 12 months In 2 cases inoperable glandular metastases occurred within 6 weeks of seeking medical advice

Of the 5 cases who are still alive the survival rate is as follows 1 case, 7 years, 1 case, 6 years, 2 cases, 4 years and 1 case, 2 years In 2 of these cases recurrences occurred in the first year after treatment and received yet more radical surgical treatment

As Ravaut points out the results of treatment vary with the stage of the disease at the time the treatment is applied If the disease is local and the treatment radical, the results are excellent, and even if the glands have been invaded there is still a chance to eliminate the disease as dissemination occurs by the lymphatic system and blood dissemination is rare

Relation of histology to prognosis —Certain conclusions may be drawn from Tables I and II embodying length of history, survival time, and histology

TABLE I

Cases which Died within 3 years after Treatment

Case	Length of history	Survival	Histology	Pigment
1	8 mths	7 mths	Papillary squamous	0
2	?	10 mths	Papillary squamous	0
3	6 wks	Under 1 yr	Papillary squamous	0
4	6 wks	Under 1 yr	Papillary squamous	0
5	3 mths	Under 1 yr	Masses squamous	0
6	7 mths	Under 1 yr	Papillary squamous	+
7	?	Under 1 yr	Papillary spheroidal	+
8	1 mth	10 mths	Papillary squamous	0
9	4 mths	3 yrs	Papillary squamous	0
10	?	3 yrs	Masses squamous	+
11	Few mths	3 yrs	Masses squamous	0

TABLE II

Cases, Congenital and Acquired, which Survived 3 years without Recurrence

18	8 mths	4 yrs	Squamous no arrangement	+
19	18 mths	4½ yrs	Papillary squamous and masses spindle	0
20	20 yrs (cong)	5 yrs	Masses spheroidal	+
21	6 mths	6 yrs	Masses spheroidal	+
22	6 wks	7 yrs	Masses spheroidal	+

Thus of the 11 cases that died, 8 had non pigmented growths and 10 had growths of the squamous type of cell, of which 7 were in papillary arrangements Of the 5 cases which survived 3 years or more without recurrence 4 had pigmented growths, and the fifth case had glandular metastases which were pigmented, although the primary growth was apparently non pigmented Growths of the "masses of spheroidal cell" type occurred in 3 of the 5 cases, as contrasted with only one spheroidal cell tumour in the 11 cases that died In this connexion it is interesting to note that 'spheroidal' cells are predominant in the deeper parts of the benign pigmented moles, as mentioned above

Although the series of cases is small the following suggestions are made (1) That the non pigmented papillary "squamous" cell growth is the most malignant (2) That the pigmented masses of "spheroidal" cell growth is the least malignant (3) The presence of pigment in a growth appears, ceteris paribus, to be more favourable than its absence

CONCLUSIONS

A review of the 25 cases of nævocarcinoma at our disposal has impressed upon us that improvement in results can only be achieved by attention to the following points —

Prophylaxis —The removal with a scalpel of out growing pigmented congenital tumours exposed to friction by shoes, clothing, or toilet

Urgency of treatment —The original tumour has been known to double its size within 48 hours and the disease should be included among the "surgical emergencies"

Radical surgical removal —However small the primary lesion, a wide excision with at least 2 in. of normal skin, together with an extensive radical dissection of the lymphatic glands and fascia is essential Where this necessitates amputation of a limb it should be advised without hesitation

Radiation treatment —The fact that many tumours are radiosensitive, although no criterion of sensitivity has been found, seems to us sufficient argument that a full carcinoma lethal dose should be applied in all cases, and even where radical surgery is possible this course of treatment should be given as a post operative measure We are of opinion that radiotherapy has much wider scope in the treatment of nævocarcinoma than its limitation to advanced and inaccessible cases

Careful and frequent post-operative observation

Our thanks are due to the members of the honorary surgical staff of the Middlesex Hospital and to Prof James McIntosh, director of the Bland Sutton Institute of Pathology for allowing us to study these cases

FUCHS SERUM PROTEOLYSIS TEST FOR MALIGNANCY

A REPORT OF 170 EXAMINATIONS

BY D LEYTON WOODHOUSE, PH D

(*From the Cancer Research Laboratory, General Hospital, Birmingham*)

MOST of the serodiagnostic methods devised for detecting malignant disease fall into one of the following groups —

1 Those involving complement fixation and related phenomena

2 Those involving flocculation or separation of protein or other elements by various reagents

3 Observations utilising injections of vaccine types of extracts

4 Tests involving analyses for specific chemical constituents of serum—e.g cholesterol and cholesterol esters, fibrin, fatty acids magnesium.

5 Physico-chemical methods involving measurement of pH surface tension osmotic resistance and electric charge determination on corpuscles, coagulation time, sedimentation rate &c.

6 Reactions dependent on enzyme changes—e.g Abderhalden's reaction and modifications, the Freund Kaminer cell cytolysis test the lipolysis test of Shaw Mackenzie and the proteolysis reaction of Fuchs

Some of these tests have proved useless in practice others, while yielding a variable proportion of correct results are far from specific and probably indicate the presence of cachexia anæmia, and toxæmia rather than the cancer which has caused them

It seemed to me probable that the reactions which depend on enzyme changes were the most likely to afford means of biochemical detection of malignant processes Some work on the augmentation of pancreatic lipolysis by serum (Woodhouse 1932) having yielded no satisfactory results I decided to try the protein enzyme test described by Fuchs (1926) which seemed to offer greater possibilities than any other It is true that the Abderhalden reaction in its original form whether carried out by chemical or physico chemical methods has been adversely criticised but actually the Fuchs test depends on a different aspect of the immunological thesis in that the observed proteolysis is produced by the interaction of cancer serum on non-cancer protein or vice versa—i e the reaction is heterologous in type

In 1930 Wright and Wolf investigated many of the details of the test Of over 100 cases examined about 86 per cent gave correct results and in 20 non malignant cases the result was correctly negative in every instance. Cadness and Wolf (1934) carried out further observations on the influence of such factors as radiotherapy heat, and alcohol Fuchs and Devrient (1932) produced evidence that the reaction is dependent on a true antigen antibody interrelationship and this was further confirmed by Fuchs and Kowarzyk in 1933 who found that intravenous injections of homologous serum containing cancer antigen caused the serum of normal men to give a positive Fuchs reaction over a period of six months Falkenhausen (1932) carried out the test in 80 cases without previous knowledge of the clinical findings and obtained correct results with all sera. Chrometzka and Gottlebe (1932) investigated 60 specimens 26 of them were from cancer patients and 24 of these proved positive while all the rest were negative They were able to enhance the proteolysis by using ultra filtered sera and obtained 22 correct results in a corresponding number of samples treated in that way They concluded that this reaction was the most dependable serum diagnostic test so far devised for cancer In 125 patients (excluding œsophagus cases) Jedlicka and Weichherz in 1934 obtained 93 per cent. correct results by the Fuchs reaction and Kafka (1934) in 56 patients had 51 correct (91 per cent) while 30 non cancerous sera yielded 100 per cent. correct results In 1933 Hing stated that in all, some 3000 tests have been carried out by various investigators using the Fuchs reaction and that correspondence with the clinical findings of 90–92 per cent. was observed.

Some of the difficulties regarding the test were removed by Fuchs (1932 a and b) who showed that the fibrin substrate might be replaced by the dried protein coagulum obtained by the trichloracetic acid precipitation of suitable serum The technique was further simplified by the application of a colorimetric method of estimation of the rest nitrogen (Fuchs and Falkenhausen 1932) instead of the original iodometric technique.

METHODS

Fuchs (1936) has lately described his test in detail and this should be followed precisely but as my own work was almost completed before his latest description appeared I will give an account of the method as I actually employed it.

The substrates were produced from the serum of healthy persons or of known cancer patients, the proteins being precipitated with 10 parts of 2½ per cent trichloracetic acid and washed several times with trichloracetic acid followed by distilled water They were dried at 40 C., powdered and tested for their proteolytic reaction on known normal and cancerous sera. A number of satisfactory proteins have been tested but two cancer and two normal preparations have been utilised for practically the whole of the tests described in this paper

For the diagnostic tests 10 c.cm. samples of blood were withdrawn from the patients by a sterile syringe after 12 hours fast and exactly 0·5 c cm of the clear centrifuged, non hæmolysed serum placed in three similar tubes 3½ in. by ½ in 5 mg of the protein substrates of normal and cancer types respectively were weighed into two of these This quantity has been shown to be a large excess so that exact weighing is not necessary The three samples were incubated at 40 C in a moist chamber for 24 hours and the proteins then precipitated by adding 3 0 c cm. of water and 0·50 c cm of 25 per cent trichloracetic acid After standing for 20 minutes and filtering through a hard filter paper 2·0 c.cm of the clear filtrate was digested with 0 5 c cm phosphoric-sulphuric acid mixture (300 c cm 85 per cent phosphoric acid + 100 c cm pure sulphuric + 50 c.cm 5 per cent copper sulphate solution) and then the non protein nitrogen estimated by adding 14 5 c cm of water and 10 c cm of Nessler solution and matching with a suitable ammonium sulphate standard in the colorimeter All these quantities were measured by means of carefully standardised pipettes and accidental contamination of all glassware was scrupulously avoided. Since the significant change is not less than 3 mg per 100 c cm the proteolysis is measured with sufficient accuracy by this means, provided that the processes are carried in identical fashion in all tests Particularly in the nesslerisation process is it necessary to avoid the presence of the slightest turbidity in the liquid. The use of porous pot is undesirable for preventing percussion in the combustion process and the addition of a few fragments of pure broken silica was found to be efficacious.

The Nessler solution was prepared from mercury iodine and potassium iodide and the alkalinity carefully standardised so that in the final colourising process the product was clear and remained free from deposit or cloud for at least half an hour The complete combustion and nesslerisation operations were carried out in the same Pyrex glass tubes (8 in by 1 in) and there was thus no error due to transference

The colour comparison was carried out in a dark room employing a lamp house and blue screen; the standards for matching were prepared from pure ammonium sulphate solution 0 1886 g per litre For comparisons with sera containing the normal non protein nitrogen value 2·0 c cm. of this was utilised in a final volume 25 c.cm

The interpretation of the analyses is based on the fact that serum from non malignant persons gives zero or slight proteolysis with normal human blood protein but a greater proteolysis with the blood protein from cancer patients Inversely a cancer serum causes a much greater proteolysis of normal protein It is necessary to exclude tuberculosis syphilis and certain chronic regenerative processes from the possibilities, since these conditions may give proteolytic reactions on normal protein They may be differentiated from the true malignant reactions by conducting blank with syphilitic tuberculous" protein &

RESULTS

In the majority of the pathological cases investigated, the clinical diagnosis was not known until after the test was completed, in many cases a considerable time elapsed before the tentative diagnosis was finally confirmed

TABLE I—*Non malignant Cases*

Tables I, II and III (*a*) (*b*) (*c*) = Rest nitrogen per 100 c.cm of serum—
After incubation alone
After incubation with normal protein substrate
After incubation with cancer protein substrate
P M = post mortem

A total of 170 sera have been examined by this method, and up to the present the diagnosis in 120 is sufficiently established (usually by operation, histological or post mortem examination) for comparison with the serum reaction These comparisons are set out in three Tables, comprising the non malignant cases (Table I), the untreated malignant cases (Table II), and the malignant cases previously treated by irradiation (Table III) These serve to indicate the variety and types of disease in the patients examined and the measure of the proteolysis encountered in all cases clinically diagnosed

The following are protocols of two tests with normal and cancer serum respectively —

PROTOCOL 1

(*a*)—*Rest nitrogen after incubation at 40° C for 24 hours*

2·0 c cm filtrate (= 0 25 c cm serum)
Final volume for Nessler comparison = 25 c.cm
Standard ammonium sulphate = 2·0 c cm = 0·08 mg
Volume of standard solution = 25 c cm
Colorimetric readings {standard = 20·0 mm
solution = 18 3 mm

$$\text{Rest nitrogen} = 0{\cdot}08 \times \frac{100}{0\ 25} \times \frac{20}{18\ 3}$$
$$= 35 \text{ mg per } 100 \text{ c cm}$$

TABLE II—*Malignant Cases*

Epithelioma of lip	34	56	40	+

N B —It has been made a rule that for a definite diagnosis of malignancy the nitrogen difference with the normal substrate shall be at least 100 per cent greater than the corresponding difference with the cancer substrate

(*b*)—*Rest nitrogen after incubation with normal protein substrate* (*N*1)

Quantities as in (*a*)
Colorimetric readings {standard = 20·0 mm
solution = 17 8 mm

$$\text{Rest nitrogen} = 0\ 08 \times \frac{100}{0\ 25} \times \frac{20}{17\ 8}$$
$$= 36 \text{ mg per } 100 \text{ c cm}$$

(*c*)—*Rest nitrogen after incubation with cancer protein substrate* (*C*1)

Quantities as before
Colorimetric readings {standard = 20·0 mm
solution = 15 3 mm

$$\text{Rest nitrogen} = 0{\cdot}08 \times \frac{100}{0\ 25} \times \frac{20}{15\ 3}$$
$$= 42 \text{ mg per } 100 \text{ c.cm}$$

Therefore —

Proteolysis due to action with {normal substrate = 1·0
cancer „ = 7·0} mg per 100 c cm

Therefore reaction is non malignant in type (Case = ovarian cyst)

TABLE III —*Radiated Cases*

Clinical diagnosis	Mg N per 100 c.cm (*a*)	(*b*)	(*c*)	Reaction
Carcinoma of cervix	30	40	30	±
Sarcoma of arm	33	38	38	—
Epithelioma of ear	36	40	42	—
Recurrent carcinoma of breast	27	29	27	—
Carcinoma of breast	31	34	34	—
	30	35	—	—
Epithelioma of ear	30	31	3	—
lip	28	9	29	—
Carcinoma of breast (amputated previously)	40	43	46	—
Epithelioma of tongue (apparently cured)	30	33	36	—
Epithelioma of lip (12 months previously apparently cured)	23	27	27	—
Rodent ulcer	19	20	20	—
Carcinoma of breast	34	38	36	—
cervix	28	29	—	—
breast	30	35	—	—
cervix	21	24	20	—
	3	40	41	—
	125	130	130	—
Epithelioma of lip	26	2	22	—
	19	2	23	—
Adenocarcinoma of thyroid	40	47	43	+
Epithelioma of face	33	34	36	—

PROTOCOL 2

(*a*)—*Rest nitrogen after incubation at* 40 C *for* 24 *hours*

All quantities as in Protocol 1

Colorimetric readings $\begin{cases}\text{standard} = 20{\cdot}0\ \text{mm}\\ \text{solution} = 20{\cdot}0\ \text{mm}\end{cases}$

$$\text{Rest nitrogen} = 0{\cdot}08 \times \frac{100}{25} \times \frac{20{\cdot}0}{20{\cdot}0}$$

$$= 32\ \text{mg per } 100\ \text{c.cm}$$

(*b*)—*Rest nitrogen after incubation with normal protein substrate* (*N* 2)

All quantities as in above

Colorimetric readings $\begin{cases}\text{standard} = 20{\cdot}0\ \text{mm}\\ \text{solution} = 15{\cdot}7\ \text{mm}\end{cases}$

$$\text{Rest nitrogen} = 32 \times \frac{20}{15{\cdot}7}$$

$$= 40{\cdot}8\ \text{mg per } 100\ \text{c.cm}$$

(*c*)—*Rest nitrogen after incubation with cancer protein substrate* (*C*1)

All quantities as in above

Colorimetric readings $\begin{cases}\text{standard} = 20{\cdot}0\ \text{mm}\\ \text{solution} = 18{\cdot}7\ \text{mm.}\end{cases}$

$$\text{Rest nitrogen} = 32 \times \frac{20}{18{\cdot}7}$$

$$= 34{\cdot}2\ \text{mg per } 100\ \text{c.cm}$$

Therefore —

Proteolysis due to action with $\begin{cases}\text{normal substrate} = 8{\cdot}8\\ \text{cancer} = 2{\cdot}2\end{cases}$ mg per 100 c.cm

Therefore reaction is malignant in type (Case = carcinoma mammæ.)

From the Tables it will be seen that the following results have been obtained —

Total cases	170
Cases with known clinical diagnosis	120
Malignant cases correct	50/53 = 94 %
Non malignant cases correct	38/42 = 90 5 %
Indefinite reactions	3
Total correct results (untreated only)	88/95 = 92·6 %
Radiated cases (positive only)	

It is of interest that the proteolysis test has been positive in external epitheliomas where the extent of the lesions was not great The reaction should therefore be of help in relatively early cases of internal cancer also; on the other hand it is not to be expected that precancerous conditions will be revealed The results are however definitely encouraging and corroborate the conclusion of Bing and Marangos (1934) that the Fuchs reaction is the most reliable of the serum methods based upon quantitative determinations

SUMMARY

In 53 malignant cases examined by the Fuchs proteolysis test 50 correct results were obtained The test also gave correct results in 38 of 42 non malignant cases The serum from patients which had previously received irradiation treatment gave negative reactions to normal protein in almost every instance

My thanks are due to the honorary staff and officers of the Birmingham United Hospital (General Hospital) for coöperation and facilities in obtaining the blood samples and for notes on the cases investigated. The work has been carried out under auspices of the British Empire Cancer Campaign (Birmingham branch)

THE INTRACRANIAL PRESSURE DURING BARBITAL NARCOSIS

BY J STEPHEN HORSLEY M R C S Eng
SENIOR ASSISTANT MEDICAL OFFICER AT THE DORSET MENTAL HOSPITAL

A STRIKING contrast is presented by the raised intracranial pressure of natural sleep and the lowered pressure during barbital narcosis This phenomenon was described by Butler (1936) who based his observations on a study of three cases under Evipan sodium anæsthesia It is of interest to confirm and elaborate these observations Three questions at once become apparent Is the pressure effect constant? Is it dependant on depth of narcosis? Is it common to all barbitals? These can be answered only by a longer series of controlled experiments Earlier reports of similar investigations are of limited value in that they fail to differentiate between partial and full narcosis For this reason the report of Epstein and Marvin (1933) is misleading in stating that Nembutal has no effect on cerebro spinal fluid (C S F) pressure Actually this is true only with small doses; it will be shown that full nembutal narcosis produces a profound fall in C S F pressure Furthermore it will be shown that this effect is not specific to evipan but is in fact common to various isomers of barbital

METHOD

The necessary experimental conditions were fulfilled in administering intravenous barbital to a series of one hundred cooperating patients

In each case lumbar puncture was performed in the left lateral position with the head supported at the same level as the lumbar spine Pressures were measured with

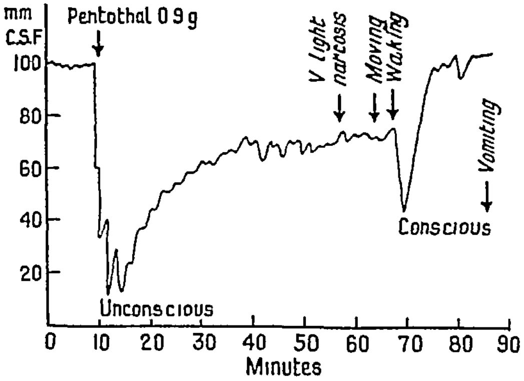

FIG 1.—Typical pentothal effect showing abrupt fall of 90 mm of C S F at moment of unconsciousness and a well marked secondary fall on waking

a vertical glass tube manometer fitted to a special needle Each observation was continued for a period of ½–3 hours and the readings were plotted at 30 second intervals on a graph The punctures were performed without an anæsthetic except in certain apprehensive patients who received a local injection of percaine In many cases there were initial fluctuations in pressure from changes in postural tension For this reason narcosis was not induced until the pressure in the manometer became steady The barbital solution was then injected by the accepted technique until the onset of unconsciousness

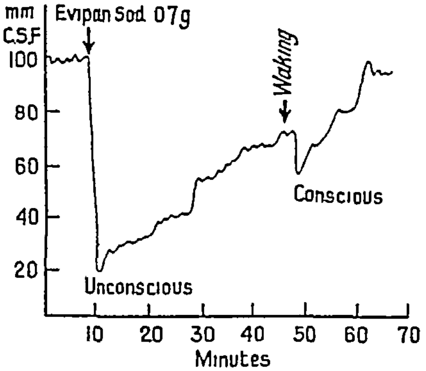

FIG 2 —Same effect with evipan showing abrupt primary fall and a slight secondary fall

RESULTS

The effect of narcosis was an abrupt fall in the C S F pressure to about half its previous level (Figs 1 and 2) This fall either preceded or accompanied loss of consciousness It was constant and indicative of full narcosis Cautious over-dosage produced a more profound fall of C S F many cases reaching zero, and two showed negative pressures (Fig 3) Conversely the administration of a subhypnotic dose of barbital failed to produce any significant change in C S F pressure

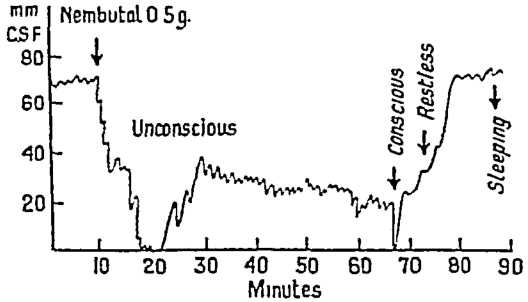

FIG 3.—Cautious over dosage with nembutal producing a profound fall in C S F pressure

In most cases the pressure rose slowly during narcosis but failed to reach its original level until the return of consciousness In more than half the cases there was a distinct second fall at the moment of waking Its exact physiological significance is uncertain, but it appears to be connected closely with the central neural control of sleep The inference is that intracranial pressure is controlled by a central hypothalamic mechanism

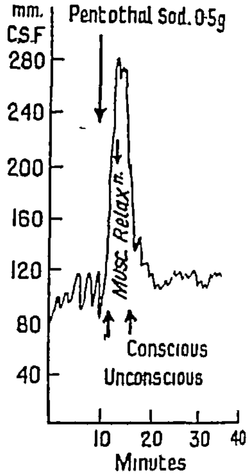

FIG 4.—Paradoxical effect of pentothal in an epileptic.

Paradoxical Effect — In the whole series only one case reacted to barbital with an atypical pressure phenomenon This peculiarity was enhanced by an exceptionally brief narcosis The effect of injecting intravenously 0 5 gramme of Pentothal was an immediate rise in pressure from 120 to 295 mm C S F (Fig 4) This peak coincided with unconsciousness and muscular relaxation There was no apparent venous congestion or respiratory obstruction which would account for the raised pressure It is of complementary interest that within three minutes the patient was awake and alert Repeated observations with evipan and pentothal showed the same effect The only other factor of likely relevance is that this patient suffered from idiopathic epilepsy The causal connexion is obscure but it is reasonable to postulate that the pathological changes sometimes found in idiopathic epilepsy might also involve the neural centres for sleep and intracranial pressure

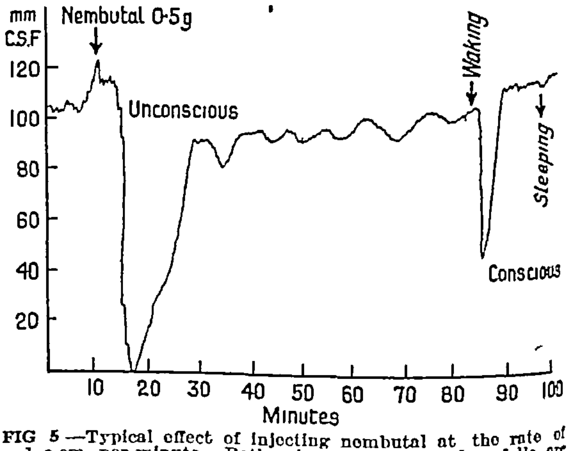

FIG 5 —Typical effect of injecting nembutal at the rate of 1 c.cm per minute Both primary and secondary falls are well marked

COMPARISON OF BARBITALS

The 100 pressure effects observed showed a remarkable uniformity It is of greater significance that this uniformity occurred not only with evipan but with four different barbitals The series comprised 30 cases of narcosis with nembutal, 30 with evipan, 30 with pentothal and 10 with Soneryl sodium Consideration of these cases permits certain tentative conclusions of which the most definite is that the pressure phenomenon is constant and coincides closely with the hypnotic effect of the particular barbital This was most pronounced in those cases that received nembutal by very slow intravenous injection (Fig 5) The pressure would remain steady during the stage of drowsiness and yawning Then usually when about 7 c cm had been injected a steep fall of C S F would accompany the sudden loss of consciousness

The *effects of barbital on the pulse respiration* and blood pressure were studied and found to vary independently of the C S F pressure Finally a study of evipan jactitations and pentothal clonus showed that these phenomena were unrelated to the C.S F pressure

SUMMARY

(1) A C S F pressure effect is described in 100 cases in which there was an abrupt fall at the onset of narcosis succeeded by a slow rise with a second fall at the moment of waking

(2) The effect is common to various barbitals nembutal evipan sodium pentothal sodium and soneryl sodium

(3) It is constant in 99 per cent of cases—the single exception being paradoxical

(4) It depends on full narcosis, and is absent with subhypnotic doses of barbital.

(5) It is suggested that C S F pressure is controlled by a central neural mechanism

Clinical and Laboratory Notes

A CASE OF LANDRY S PARALYSIS

By A V Russell, B A Camb M.B Liverp

Landry s paralysis is described as beginning with weakness of the legs which often progresses rapidly to complete paralysis Trunk muscles are next affected and then within a few days or even hours the arms The neck muscles are next attacked and finally the muscles of articulation, deglutition and respiration Reflexes are lost but muscles neither waste nor show electrical changes Sensory symptoms are variable and sensation is usually intact though there is sometimes tingling numbness and hyperæsthesia The disease is very often fatal

A girl of 20 was brought to me complaining of feeling tired, of numbness and tinging in her hands and feet of an occasional sensation as though a ball was rising in her throat and of a feeling of depression which made her cry She looked healthy and athletic Her knee- and arm jerks were exaggerated; the pupils reacted briskly to light; she had slight tremor of the hands, and her numbness and tingling appeared to be of the glove-and-stocking type Her hands and feet were cold, the pulse rate 7* per minute the temperature subnormal the tongue clean, the throat healthy and the heart and breath sounds normal She seemed depressed, but not unduly emotional I thought the case was one of nervous debility gave her a bromide and valerian mixture and told her to lead as normal and cheerful a life as possible

Two days later I was called urgently about 8 P M She had been taken to a point to-point meeting that day (which I shall call the first of her illness) and there after a time her legs had failed her On reaching home it was found that her legs had become useless she could *not* walk even with assistance When I saw her the knee and ankle-jerks were absent the Babinski reflex was slight and doubtfully flexor She could just move the toes the ankles very slightly and her knees and thighs not at all The abdominal reflexes were hard to elicit the arm jerks brisk, and the eyes reacted normally to light Temperature 97 F pulse rate 84 She said she had pins and needles in her lower limbs but could feel me touching them with a piece of cotton wool and could appreciate *the difference between the point* and *head* of a pin lightly applied to them

There was no history of a recent attack of influenza or of sore throat and no indication of alcoholism or of contact with any form of nerve poison there was no blue line on her gums, and her throat still appeared normal I called in a consultant colleague and when he arrived about forty minutes later she was no longer able to move her ankles or toes and her lower limbs were flaccid and powerless Nevertheless she was curiously placid and *undisturbed* She was taken at once into a nursing home and on lumbar puncture cerebro-spinal fluid came out under considerable pressure—unluckily contaminated by several drops of blood.

The course of events thereafter was as follows *Second day* Abdominal reflexes abolished; weakness and tingling in hands *Third day* Arm jerks absent patient just able to move arms, but unable even to hold a spoon *Fourth day* Arms and hands quite paralysed slight pain and stiffness in neck pupil reflexes sluggish Blood *count showed* —

Red cells	4 170,000 per c.cm	Polymorphonuclears	76
White cells	11 100	Lymphocytes	[illegible]
Hæmoglobin	73 %	Monocytes	1
Colour-index	0 87	Eosinophils	Nil
		Basophils	1

No morphological abnormalities of red or white cells.

On the *sixth day* she complained that she could not move her head on the pillow that she saw double and had some difficulty in swallowing Her face was expressionless; she spoke in a dull slow voice seemed drowsy and took a long time to answer questions The eyelids drooped, and the pupils reacted to light very slightly if at all During all this time she had been very constipated and found it difficult to pass water After the third day she had an enema every day for a week but catheterisation was only necessary once—on the fourth day *Seventh day* Though her face still lacked expression and she continued to be drowsy there was some improvement in swallowing she could move her head very slightly *from side to side*

Eighth day Some embarrassment in respiration which fortunately soon passed off *Ninth day* Slight return of movement in hands and fingers and increased movement of head and neck; face still expressionless drowsiness and diplopia still present *Eleventh day* Much more movement of hands possible facial expression more alert head moved easily from side to side on the pillow; swallowing without difficulty; left abdominal reflex returned *Twelfth day* Arms moved with some difficulty; patient said they *felt extremely heavy and* tingled *Eighteenth day* Arms moving fairly well hand-clasp weak Could move feet a little and was nearly able to lift head from pillow Double vision had gone pupil reflexes normal; abdominal reflexes normal Massage and electrical stimulation of muscles now begun *Twenty fourth day* Feet and ankles moving much better; able to move knees slightly *Twenty fifth day* Slight knee-jerk response

From now on progress towards recovery was fairly steady though on the thirty fourth day after sitting up in a chair there was a return of paresis in both hands and the patient complained of a tingling sensation in her face; this lasted for four days She began to walk with assistance on the forty-second day and at the end of eight weeks was getting about by herself with a stick Save that she still had a weak hand clasp and was easily tired could be considered almost recovered. The illness was apyrexial throughout

Lumbar puncture was performed every day for the first week, every other day till the eighteenth day once again on the twenty fourth day and a final puncture on the thirty fifth day after the return of paresis in the hands

The first sample of cerebro spinal fluid was blood stained but cultures yielded no growth, protein was 500 mg per 100 c cm globulin in excess, chlorides 0 71 per cent , sugar 0 075 per cent The second sample was browny yellow in colour, and again protein was in gross excess—over 400 mg per 100 c cm The protein content remained at over 400 mg till the twenty fourth day, when it dropped to 140 mg , and the C S F was almost clear At no time were there more than 4 or 5 white cells per c mm The report on the final sample taken on the 35th day day was "Fluid clear , protein 180 mg per 100 c cm , globulin in excess , chlorides 0 7 per cent , sugar 0 05 per cent , cells under 1 per c mm "

At the beginning of her illness the patient was given a mixture containing Hexamine 10 grains thrice daily, but it was discontinued on the fourth day because she disliked it, and it seemed clear that lumbar puncture was the only really useful treatment She said she felt better after each puncture On occasion aspirin or a compound phenacetin tablet was given for discomfort but very little was ever needed Early in the illness we made sure of the availability of an automatic respirator in case the muscles of respiration should fail, but this was not needed

When I saw the patient three months after the illness was over she was in excellent health, without symptoms or disabilities

ACUTE DUODENAL OBSTRUCTION

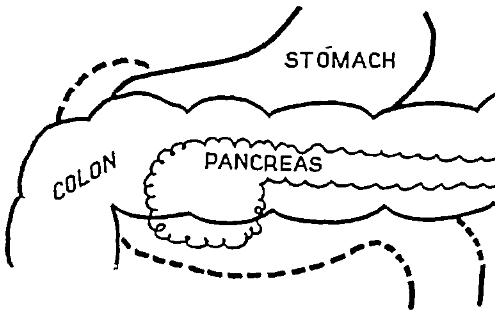
By K S Nigam, M D Allahabad, F R C S Edin , D T M

PROFESSOR OF SURGERY IN THE UNIVERSITY OF LUCKNOW INDIA

It is an old saying that "the abdomen is a temple of surprises", and with all the modern methods of clinical investigation at his command there are still occasions when a surgeon making a laparotomy has little idea of what he will find

A B , aged 16, Hindu, male, vegetarian, unmarried, was admitted to our surgical wards at about 10 A M on Jan 16th, 1936, complaining of three days' pain in the upper part of abdomen and two days' vomiting The history was that with no antecedent trouble whatever, on the morning of Jan 13th he went to defæcate and had a scanty evacuation , he did not strain in the act Simultaneously he felt a mild colicky pain across the upper half of abdomen, and with frequent exacerbations this persisted throughout the day and the night following He stayed in bed, stopped all food, and took some carminative mixture On Jan 14th and 15th the pain became more frequent and severe He vomited about six times on the 14th and eight times on the 15th, and in the evening of the 15th he had an enema without result A particularly restless night followed and he was sent to hospital The only point of interest in the previous history was that two years ago he had suffered from a similar pain which passed off in a few hours, without vomiting

Examination —The patient was thin but wiry his expression was pinched and anxious The abdominal walls were receding but moved freely on respiration The abdominal reflexes were normal and there was no cutaneous hyperæsthesia The epigastric and right hypochondriac regions were tender to deep pressure There was no guarding of muscles but the supraumbilical part of right rectus muscle offered greater resistance to palpating hand than elsewhere During examination an indefinite round mass about 2 in in diameter was felt a hand's breadth to the right of umbilicus , it was tender, moved with respiration varied in size and was tympanitic Within 10 minutes this lump had disappeared and no further trace of it could be detected by any manœuvre or manipulation (It was probably a segment of bowel in spasmodic contraction) Rectal examination showed nothing abnormal , two high rectal enemas, at an interval of an hour, gave no result beyond return of the fluid. The pulse rate was 62–68, the temperature 96 0° F, the respiration rate 24, and the blood pressure 118/64 The urine (spec gravity 1026) gave a positive test for acetone but not for diacetic acid. The leucocyte count was 10,000 per c mm (80 per cent polymorphs and 20 per cent lymphocyte), no abnormality in the number or size of red blood corpuscles was detected



Findings at operation The interrupted line indicates the extent of the hæmorrhagic effusion

Treatment —In view of acetonuria, vomiting, and lack of proper nursing from the start of illness, expectant treatment was adopted with Fowler's position, administration of 5 per cent glucose in saline by proctoclysis as well as intravenous drip, and turpentine stupes to the abdomen In the afternoon the patient had two more severe attacks of colic and vomited twice he passed no fæces or flatus, and the abdomen was slightly distended in the middle His pulse rate rose to 116 and his temperature to 101° F On a provisional diagnosis of acute high intestinal obstruction laparotomy was performed at 6 P M on Jan 16th

Operation —Entry through right paramedian umbilical incision Collapsed jejunum and ileum encountered. No free fluid in peritoneal cavity A transversely elongated oval purplish black mass was found under the transverse colon which was held up with empty stomach and liver pushed above under the ribs This mass was tympanitic The peritoneum on this mass below the transverse colon was incised, and 8–10 oz of tarry blood escaped On mopping this away normal pancreas and duodenum were exposed and thoroughly examined by incising the peritoneum widely , but no abnormality such as a *true cyst of the* pancreas, diverticula, or *ulcers* of the duodenum was detected There was no active bleeding Simultaneously the jejunum assumed a filled up appearance demonstrating that the effused blood had caused mechanical obstruction of the duodenum The superior mesenteric vessels or their branches were not pressing on the duodenum The hæmorrhagic effusion was found to extend proximally to near the pylorus and distally to about an inch beyond duodenojejunal flexure The abdomen was closed in the usual way after bringing out a drain of rubber tissue *through a stab wound* in the right loin across the right renal pouch of Morrison Recovery was uneventful, the drain being removed in 24 hours

Special investigation —On the 16th, after the operation, the bleeding time proved to be 3 mins 45 secs next day it was 3 mins 40 secs The diastase content of the urine, estimated in the pathology department of King George's Medical College, was 20 units per c cm, (Jan 17th), and the pathologist examining tissue, &c removed at operation, described them as blood clot covered with endothelial cells which are probably derived from the peritoneum—a peritoneal blood cyst " Clot culture from the contents of the cyst was sterile after 24 hours' incubation No microfilariæ were detected in the night blood Loewi's test was negative Acetone disappeared from the urine on Jan 20th. Opaque meal skiagraphy on Feb 7th by Dr Raghunandan Lal showed a J shaped type of stomach with no indication of ptosis, niche, or accessory pocket A certain amount of gastric residue was present after 1¼ hours The meal passed rapidly through the first and second parts of duodenum but was held up again in the third part of duodenum. No evidence of ulcer

In this case there is no history of trauma except that the pain started during defæcation which may imply some straining though the patient denies it If he did strain why did hæmorrhage occur round the duodenum? No hæmorrhagic diathesis was indicated and the bleeding time was normal (platelet count not done) The head and body of pancreas were carefully exposed but no abnormality was found there was no fat necrosis or sign of pancreatic insufficiency or irritation. No gastro-duodenal ulcer was found at the operation or was indicated by skiagraphy The cause of the illness thus remains undetermined The patient is at present in excellent health

MEDICAL SOCIETIES

WEST LONDON MEDICO CHIRURGICAL SOCIETY

This society met on Jan 8th at the Vere Hotel with the president Mr **Neil Sinclair**, in the chair and Mr **Eric Pearce Gould** president of the Medical Defence Union opened a discussion on the

Defence of Negligence Actions

A patient had a right he said to expect that his doctor would exercise reasonable skill and care the failure to do so was negligence Complaints of medical negligence were increasing for various reasons The old time mutual confidence between doctor and patient was unfortunately lessening lay people knew more about medical matters particularly about X rays there was a certain news value in the doctor s peccadilloes and the publication of accounts of actions against doctors encouraged others to complain The gravity of negligence actions was *also increasing partly* because juries tended nowadays to award very high damages and partly because recent legislation had extended liability for the results of negligence beyond the person of the doctor to his estate after his death. An action could be brought against a firm of partners for the negligence of one member and it was therefore essential that each member should belong to a defence society and convenient that all should belong to the same society

Negligence actions he continued fell into four groups the first of which comprised actions brought out of pure malice to avoid the payment of fees A summons served by the defence society would often bring payment sometimes outside the court immediately before the hearing Secondly when the act was really negligent a settlement must be made on the best terms at the earliest possible moment Third came the actions in which there was prima facie evidence of negligence but from a medical point of view a good defence If the plaintiff were reasonable it might be wiser to settle or to deny negligence prepare the defence await a moment when the patient s demands were not quite as exacting as they had been and then settle the defence might on the other hand be good enough to take into court with a fair chance of success One cause of such actions was the transfer of a patient from one doctor to another in the middle of a course of treatment—e g a plaster splint for a fracture—planned by the first doctor when it failed the patient might blame the second doctor without good cause Sometimes the society considered the defence to be excellent but the doctor feared that even a successful result would injure his practice; the society would then try to meet his wishes

The fourth and last group consisted of cases in which negligence had clearly been committed but the doctor was not to blame a class which seemed to be multiplying Until a generation ago it had been generally accepted by the profession that the doctor was responsible for all that happened in a case and not so very long ago the protection societies had succeeded in establishing for practical purposes the principle that an anæsthetist was responsible for his own errors and had exonerated the surgeon from liability for injury in matters within the anæsthetist s particular province The time might have come for recognising the responsibility of other assistants. Modern medical work increasingly needed the coöperation of a team of workers each trained in his or her own particular duties It was right and proper that such duties should be delegated to the carefully trained assistants of to-day While no surgeon could be exonerated from seeing that the members of his theatre team were properly trained most medical men would feel that if he did this he was then entitled to rely upon his assistants for seeing that the swabs and instruments were correctly counted A South African appeal court (Van Wyk v Lewis 1924 S.A.L R 438) had given a ruling exonerating the surgeon in a case where a swab had been left in after the theatre sister had reported correct A surgeon ought also to be entitled to rely upon the ward sister not to burn the patient with hot water bottles after he returned to the ward or to remove in due course drainage tubes inserted at the operation A surgeon should not carry quixotry so far as to take the blame for a nurse s negligence merely because her shoulders were weaker than his

In conclusion Mr Pearce Gould suggested that all doctors ought to realise the many pitfalls of medical practice and be increasingly careful A doctor who felt conscience striken should not commit the error of telling the patient how blameworthy he considered himself A doctor should never criticise before the patient or his friends the treatment of another doctor and most important every practising doctor should belong to a medical defence society and pay his subscription regularly; 20 per cent of members were late every year in paying their subscriptions and therefore fell out of benefit for a time A doctor faced with a complaint of negligence should consult his society at once and the first reply to any communication he received should be dictated by their experience rather than by his feelings of the moment Finally having consulted his society the doctor should do what he was told

Mr **C T Le Quesne** K C said that the possible defences to an action for medical negligence were first that there had been negligence but the doctor had not committed it as when a pair of forceps had been left in a patient s body at a previous operation (Crotch v Miles[1]) Secondly the doctor might plead that although the patient was not satisfied he had taken reasonable care and used reasonable skill and had therefore not been negligent; this defence particularly applied in cases where the medical evidence conflicted Thirdly, he might plead that he was not responsible for the negligence of another person The court would always have to hear the evidence, including evidence of the custom governing the particular operation or treatment, and decide whether in all the circumstances the responsibility rested with the doctor or with one of his assistants

DISCUSSION

Mr W McAdam Eccles said that many cases were prevented from coming into court by the good offices of the defence societies Nursing coöperations varied in the steps which they took to insure their nurses Some, whose nurses were legally their servants, insured themselves against third party risks He asked who was responsible when a coöperation lent a nurse to a hospital for service in one of its private wards the practitioner who gave her orders, the hospital, the coöperation, or the nurse? Other coöperations, besides insuring themselves, insisted that each nurse should take out an insurance policy The routine of an operation became so much of a habit that it was easy for the surgeon to detect negligence in its performance by any member of the team He himself never left a nursing home or house without making sure that there was nothing in the patient's bed likely to do damage If a doctor was called to give evidence against a colleague he must not hesitate to tell the truth, as he was bound to do by his duty to his profession, the State, and the law

Mr G B Woodd-Walker said that the surgeon was peculiarly open to complaints of negligence in his treatment of fractures The out patient surgeon, treating a patient who was dissatisfied with the treatment of his general practitioner, often found great difficulty in communicating with the doctor without the patient's knowledge It was very important that the hospital surgeon should stand by the private practitioner and not allow the patient to have access to records and films which might possibly support a charge of negligence

Dr Reginald Perkins asked whether a doctor could be charged with negligence for leaving with the patient enough tablets of a hypnotic drug to enable him to commit suicide

Prof V B Green-Armytage related that a married woman, a deaf mute, whose husband was also a deaf mute, had been admitted to his hospital desiring ligation of her Fallopian tubes on eugenic grounds, her husband joined in the request The hospital governors had forbidden the operation, taking the view that it would constitute the criminal offence of maiming Another hospital, however, had admitted her and had allowed an honorary surgeon to perform the operation, to the great and permanent satisfaction of the couple On another occasion he had sterilised, with the consent of her husband a woman who had spent six months in Bethlem Royal Hospital with puerperal mania The man had later threatened an action or prosecution but had been dissuaded by the defence society Prof Green Armytage expressed fear that he had offended against the law or against the husband's legal rights, but mentioned that he had safeguarded himself by performing only a temporary sterilisation—burial of the fimbriated ends in the broad ligament—which could be undone at any time

Mr D Harcourt Kitchin said that there was little authority in this country governing the vicarious liability of a surgeon Perionowsky *v* Freeman (1866, 4 F and F 977) seemed to lay down that the surgeon could not be held responsible if a nurse carried out his orders negligently in circumstances in which he could not supervise or control her actions, when the duty was one which he could properly delegate to her In the case of Van Wyk the court had found the practice of delegating the counting of swabs to the sister to be reasonable, that she was an independent assistant, and that the surgeon was entitled to rely on her count Even that judgment had not, however, exonerated the surgeon for every negligent act of one of the team, and it could only be applied to the particular circumstances of that case In Ingram *v* Fitzgerald[2] the New Zealand Court of Appeal had decided that the surgeon was not responsible for the mistake of a nurse in painting the patient's body with iodised phenol instead of tincture of iodine Such decisions merely laid down the principle that in certain circumstances a surgeon might not be responsible for the negligence of an assistant, they did not do more He asked Mr Pearce Gould what measure of immunity the profession demanded He could not imagine Parliament passing an Act exonerating all surgeons from liability for all negligence of a member of the theatre team, nor any decision of the House of Lords which would extend beyond the facts of the particular case. It seemed probable that the surgeon would always be open to actions for vicarious negligence, and that his legal position would be gradually improved as successive decisions exonerated him in particular sets of circumstances The liability of a coöperation for the negligence of one of its nurses must, Mr Kitchin thought, depend upon the contracts which the patient had made with the hospital, the hospital had made with the coöperation, and the coöperation had made with its nurse In Hall *v* Lees (1904, 2 K B 602), where a patient sued a coöperation because one of its nurses had burnt her with a hot water bottle, the court had found that the coöperation had only undertaken to supply a competent nurse, and not to nurse the patient through her agency The answer to Mr McAdam Eccles's question would therefore probably be that the nurse was in any case liable, the coöperation was not liable if it only undertook to supply a competent nurse, the hospital was not liable because she was presumably doing skilled work which its governors could not supervise or control, and the practitioner was not liable for the same reason He still maintained that the provision of the Law Reform Act, 1934, which gave an aggrieved patient a right of action against a doctor's estate, was not likely to be quite so disastrous as had been represented, because the estate could not claim damages for loss due to the death itself He could not see what right of action a widow could have against a doctor who entrusted her husband with a lethal number of medinal tablets, for she could not claim for loss due to the death, and the patient could not have claimed damages for injury caused by his own act He did not know of any enactment or provision of law which would make a gynæcologist liable to a criminal prosecution for sterilising a woman on medical or eugenic grounds, for the old offence of maiming had consisted only in impairing the efficiency of a man as a soldier A sterilising operation performed without the consent of the woman of course gave her a right of action for assault, as would any other operation

The President mentioned that he had himself been sued for damages caused by a nurse with a hot-water bottle but the Lord Chief Justice had directed the jury that he had no case to answer His practice had not suffered but had increased after this success

---

[2] *Brit med J* 1937 1 46

Dr H H SANGUINETTI asked what investigations a doctor might reasonably be expected to perform in deciding whether an operation was necessary and suggested that in many cases a white cell count should be made

Mr HOWARD STRATFORD asked how a doctor should protect himself against an action for not ordering a radiological investigation when the patient had refused to have one

Dr GERALD SLOT said that a prolific source of complaints against physicians was notification of infectious disease Many deaths attributed to the anæsthetic were really due to prolonged manipulation Checks against wrong dispensing were in many nursing homes not carried out as carefully as they might be

REPLY

Mr PEARCE GOULD deprecated the use of bankers orders by members of defence societies for the member might change his bank and forget to make a new order and they were harder for the office staff to check He considered that individual insurance by nurses would lead to many actions being brought which otherwise would not be heard of Hospitals should take steps to prevent patients having access to the notes of their cases In every case in which the doctor considered a skiagram should be taken and the patient refused he should at once put his opinion into writing either by sending a letter to the patient and keeping a copy or by making a note at the time in his own records The doctor must always do what he thought best for his patient, regardless of the possibility of legal complaint The Law Reform Act 1934 was a serious danger to the relatives of deceased doctors and both defence societies now undertook to defend an action brought against the estate of a late member

---

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION

AT a meeting of this association on Jan 8th Dr JOHN LAMBERT (Wellington) the president took the chair and Dr E KAYE LE FLEMING opened a discussion on the

Education of the Body in Public Secondary and Preparatory Schools

The first question likely to be raised he said was that of nutrition In *schools of these three kinds* it was improbable that the food would be insufficient in quantity; but even the best diet sheets failed to disclose its quality and the way in which it was cooked and served Unfortunately there were still schools at which fresh fruit was an extra and had to be paid for Growing boys needed a lot of sugar and one explanation of the popularity of the tuck-shop was that boys were conscious of the sugar deficiency of their ordinary diet Spacing of meals was also of prime importance yet he knew one large public school at which after their 1 o clock meal the boys played Rugby football had a shower bath changed re-entered school took their work and got nothing to eat until 6—which he regarded a monstrous As for fresh air its full value would probably not be recognised even in the medical profession without experience of life in a sanatorium The ordinary school curriculum did not allow enough margin for this and there was still a great deal of unhealthy overcrowding in schools where there were dormitories and each boy did not (as at Eton and Harrow) have a room to himself. The main infections in school life were droplet infections spread by coughing and sneezing and in one school with a high sickness rate insistence upon three feet between beds had led to great improvement As to clothing most people wore too *much, though he must make a large excep*tion for the many girls and young women who had adopted a minimum of clothing to their great physical advantage Impact of air on the skin was a real healthy stimulant

The body regarded as a machine controlled by the will, was capable of an almost infinite variety of development especially during the plastic school age But the object of physical training in schools was not to turn out contortionists or figure-skaters but to produce a muscularly balanced body capable of much purposeful energy with a minimum of fatigue; or as the report of the British Medical Association said a balance of body mind, and soul. This balance was well seen in birds in flight slow motion pictures of which were very instructive The first step towards getting the new ideas on physical education incorporated into school life was to induce head masters to believe in its value; at present generally speaking they were insufficiently convinced Who should educate the educators? The interesting attempts now being made to ascertain how much a boy will learn in a given time devoted to mental education compared with what he can learn if part of this time is devoted to physical instruction promised valuable results Head masters would say and with justification that until parents wanted physical training it would be difficult for masters to supply it The fact was that the school doctor must educate his head master and the head master must educate the parents Opposed as Britishers were to dictators two dictators yet held sway the head master and the coroner

Another difficulty concerned the relation of physical education to games The two should be linked together; they could not be carried out under two masters for these would probably be at loggerheads Perhaps the greatest difficulty of all was to find the right teachers Who was there who could go into boys schools and teach physical education on modern lines? Where could such teachers be trained? The answer was practically Nowhere in the country It was very different in regard to girls schools It was a dreadful thing to confess that the remedy was to take a course in Sweden All through the B M A report on the subject it was made clear that physical education needed close coöperation between teachers and doctors since the medical was the most important side But the doctor had almost no opportunity of getting acquainted with physical education though this was a very important part of preventive medicine Science had been defined as measurement yet there was no adequate measure or standard of physical fitness In the simple matter of heart tolerance to exercise each medical man had his own standard and method of test which though of value to himself was of no value to others It was to the universities one looked for help in this matter but so far in vain

The PRESIDENT said that for many years there had been four or five large schools for training teachers of physical education in girls schools whereas for men he knew of only the Leeds Training College

Dr C Watney Roe (St Paul's) said the training contemplated was far more important than mere physical jerks As to diet, though no one in England could be said to be starving there was a striking absence of calcium, iron, and essential vitamins in many diets The work of Dr G E Friend, at Christ's Hospital, showed excellent results achieved at a school by a generous and well balanced diet —Dr Arthur Davies mentioned the work of the College of Hygiene and Physical Training at Dunfermline and Edinburgh It was extraordinary, he said, that physical education should have been so much ignored by the universities —Mr Crocker contended that only those able to have unlimited fresh air could keep their bodies fit —Dr A H Macdonald (Dr Barnardo's Homes) said that, for teaching physical exercises, his institution had secured a very good type of man from Aldershot, and they were very successful with the children

Dr L R Lempriere (Haileybury) said he believed that most of the infections at school did not take place in crowded dormitories at night, but in the house and classrooms during the day It would be a boon if someone would give a handsome contribution to found physical training centres at universities He agreed that until head masters and assistant masters were thoroughly interested in this matter, advocates would be simply marking time His only criticism of the B M A report was the demand that three periods per week should be spent by all youths on this subject, that was asking too much, and was unlikely to be accepted.—Mr Turner advocated a compulsory half hour of sleep or rest in the day

Dr Elwin Nash spoke of the importance of having a proper system of heating in schools He asked whether any figures were available to show the effect of shortening the periods of instruction, comparable with those issued by the Industrial Fatigue Research Board He meant a break in the morning for cocoa and in the afternoon for tea He remarked that he had never met a physical training teacher who had made the boys understand the why and wherefore of what they were required to do —Dr C K Attlee held that the physique of girls was now much better than that of boys —Dr E B Morley said he had often asked himself what was the aim of all this physical fitness, what was the boy making himself fit for? The average boy did not look beyond his ability to play games Was he not, in many cases making himself fit to endure sitting on a stool in a close office many hours a day? Or sitting in the ill ventilated law courts listening to endless arguments? In arriving at the proportion of men unfit for the Army at the outbreak of the late war it must be remembered that much of the examining was done by old doctors who considered the presence of a heart murmur meant absolute incapacity and rejection Not only was it necessary to have regard to what boys were being made fit for, but every effort should be made to render occupations healthy

Health Centre at Blackpool.—The site of the old Victoria Hospital is being acquired for £30 000 by the Blackpool health committee for use as the health centre of the borough

Lucy Baldwin Maternity Home Stourport —On Jan 5th Mr Baldwin opened further extensions to this maternity home which was the gift of Sir Julien Cahn to Mrs Baldwin who presented it to the Worcestershire county council Sir Julien Cahn has also met the cost of these extensions

ROYAL SOCIETY OF MEDICINE

SECTION OF THERAPEUTICS

At a meeting of this section on Jan 12th, with Dr Dorothy Hare, the president, in the chair, a paper on

Protamine Insulin

was read by Dr H C Hagedorn (Copenhagen) He began by speaking of the change brought about by the introduction of insulin. At first, he said, its success was so great that nobody thought of improving the remedy, but an improved technique had been found desirable in the severer cases with considerable oscillations in blood sugar, which needed careful and frequent examinations The oscillations could be modified by appropriate distribution of the diet and also by better timing of the insulin effect through modifications in the insulin preparations themselves This second method had been thought of as early as 1923, and his institute had taken much interest in it ever since Three ways of retarding the effect of the insulin had been tried first, the emulsification of insulin solution or the suspension of dry insulin in oil, which had not seemed applicable in every case, secondly, the injection of a vasoconstrictor with the insulin, thirdly the injection of the insulin as a more or less insoluble compound The rate of absorption of both soluble and insoluble preparations depended on the concentration and on the volume The insoluble compound differed from the soluble in that the dose could be varied, without altering the volume or the concentration in the liquid phase, theoretically an injection of a suspension of an insoluble compound gave a constant rate of absorption until all the particles were dissolved He had restricted his experiments to those substances that were destroyed or excreted rapidly, fearing that other compounds would sooner or later cause unpleasant surprises Some experiments with tannic acid compounds had been abandoned because of local reactions, but protamine insulins had been found to be non toxic in far greater doses than those to be used in treatment, and had a prolonged action clinically Many protamines had been tried, and salmiridin (obtained from the rainbow trout) had been chosen as suitable Researches by Mr Krayenbuhl into the physical chemistry of protamine insulin compounds had thrown light on the effect of mixing doses of the soluble and insoluble preparations If solutions of protamine and insulin were mixed in varying proportions one proportion was found to which the further addition of either substance (after the production of the first precipitate) would cause the same amount of further precipitation This proportion, called the isophane proportion, was peculiar in that the ratio of insulin to protamine was the same in the precipitate and the solution The isophane proportion was altered by the presence of small quantities of zinc which also prolonged the action of protamine insulin The amount of zinc used in practice was so small that it was generally considered harmless, but the speaker himself only used it for those for whom the protamine insulin alone was not satisfactory The precipitated protamine insulin was stable for many weeks under ordinary conditions and for months in cold storage Dr Hagedorn said that objections had been raised to the name protamine insulinate, because the ending "ate" implied that insulin was an acid radicle In view of the very complicated chemical nature of the substance he had dropped the ending and now spoke of protamine insulin.

Caution had prompted him to treat only a few cases with the new material for the first year Dr N B Krarup had tried the substance in hospital under controlled conditions, carefully observing the blood-sugar glycosuria, and acidosis Graphs taken from these results showed the relatively quick action of the soluble insulin and the more even action of the insoluble The protamine insulin had been used in one daily dose and he thought that all who regarded protamine as harmless would agree that the compound should be used as soon as it was apparent that one daily dose of plain insulin was insufficient Protamine insulin was suitable for evening doses but its effect stopped abruptly and sometimes the evening dose had to be postponed for this reason. Ordinary insulin might be better suited to the requirements of daytime in some cases especially in children, a second dose of the insoluble preparation was useful. The combined use at one time of both types was being tried both in combined and separate injections Patients having protamine insulin said they felt better and less tired and that they had ample warning of hypoglycæmic symptoms which also tended to last longer Surgical cases had been easier to deal with, and Graves's disease occurring in three diabetics had improved astonishingly Many patients who used to be brought to hospital frequently in hypoglycæmic or semi comatose states had kept out of hospital. Treatment however was not successful in every case for some did not react typically

Dr O Leyton referred to the leading part taken by Dr Hagedorn in the evolution of insulin therapy and the boon he had conferred on diabetics by supplying a compound which for many converted a life of hazard into one of comparative monotony Those who had much experience of protamine insulin confirmed Dr Hagedorn's results but some might be unlucky with their first cases In over half of his own cases the prolonged action of protamine insulin had prevented severe hypoglycæmic attacks and also the rise of the blood sugar in the early morning It had enabled him to give only two doses a day to some patients who in spite of much juggling with food had required three or even four doses of insulin hydrochloride a day Single doses of protamine insulin given first thing on waking had kept the blood sugar level to between 0 08 and 0 15 per cent for twenty four hours occasionally this had been astonishingly successful even when a single dose of more than 40 units had been required Naturally the distribution of carbohydrate had to be adjusted about 35 per cent had been given at breakfast two hours after the injection and 50 10 and 5 per cent respectively at lunch tea and the evening meal. The total carbohydrate was often well over 200 grammes In some however hypoglycæmia developed at about 11 A M and in others the insulin was ineffective The variable action of protamine insulin probably depended partly on the site of injection but a few observations of the effect of intravenous intramuscular hypodermic injections and those into adipose tissue had not accounted for the variation Dr Leyton thought that if a patient's condition was well controlled upon two doses of insulin hydrochloride a day not exceeding 12 units in all no change should be made unless for some special reason he could not give himself or be given an evening dose For those who were improving and no longer needed 12 units in two doses a single dose of protamine insulin was advisable

Dr W W Payne said that one girl who had been under his care for a long time at the Hospital for Sick Children Great Ormond street had changed conspicuously since being put on protamine insulin She had been a severe case and very nervous, but now stood up to the accidents of life in a much better way Although it was still hard to keep diabetic children sugar free and although the change to protamine insulin wrought no obvious improvement in physical condition when this was already good the patients themselves said they felt much better He had been trying one daily dose on most of his child patients and often found that they remained sugar free through the night Unlike Dr Leyton he had spread the carbohydrate evenly through the meals He had had one protamine reaction after using freshly precipitated material and had since avoided preparations which had not been made at least a day before. He asked whether a stronger solution could be made A dose of 60–70 units occupied nearly 2 c cm. and was a bulky dose to give to little children

Dr George Graham had had some patients suffering from hypoglycæmia after protamine insulin some of them who had formerly had no warning told him that they could now tell when an attack was imminent He thought the new treatment would be very useful for patients with big variations in blood sugar He wished there were a third type of insulin quicker in action than the hydrochloride

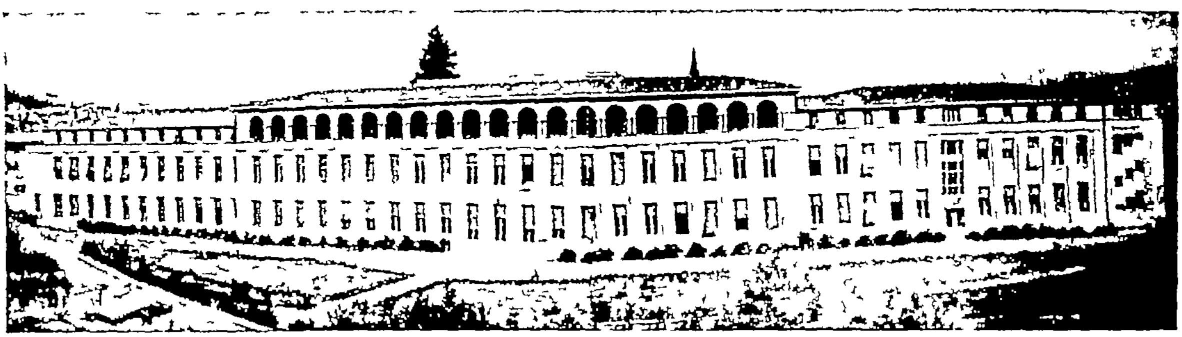
Dr T Izod Bennett had been able to reduce the total amount of insulin his patients were receiving although they were having only one injection a day He had been able to abolish the hypoglycæmia which had commonly developed before breakfast The change in temperament noted in his patients since using protamine insulin had shown him how much the fear of hypoglycæmia had haunted them before and how it had been a cause of nervous irritability He thought the introduction of new forms of insulin was going to make the physician's work much harder He avoided the use of two kinds of insulin in one patient, for he felt that if a patient had two kinds to give himself accidents were bound to happen sooner or later Slow insulin had come to stay but he hoped doctors would not use two kinds at once He expressed regret that the protamine insulin should all come from abroad and that the British manufacturers always walked in the rear of other countries.

Mr F H Carr D Sc speaking on behalf of the manufacturers, said in reply that the British firms were collaborating in the production but had delayed putting protamine insulin on the market at Dr Hagedorn's request until a uniform and well tried product could be issued There was a patent on the preparation which except by the courtesy of Dr Hagedorn or by contravention of the patent prevented them from making it

Dr Hagedorn thought a stronger solution of protamine insulin might be made but he was not sure that its action would be so prolonged A single daily dose was the ideal but infection and other causes often made two doses preferable It had been said that diabetic patients sailed uncharted seas; and he thought the same might be said of their doctors He wished them a happy voyage

---

New Surrey Hospital —The Surrey County council is proposing to erect a large hospital in Carshalton with accommodation for 53[illegible] patients to meet the growing needs of the county The nurses home will house 340 nurses



AN ATHENS HOSPITAL

The Marika Eliadi Maternity Hospital was given to the city of Athens by Madame Helena Venizelos in memory of her friend whose name it bears It is a three storeyed building which stands in beautiful gardens looking towards Mount Hymettos The large square entrance hall is of rose-coloured marble, and from it white marble stairways lead to the first floor where there are wards for patients who pay small fees or none at all The colour scheme on this floor is pink and white and each room accommodates ten beds and their cots They are large and well ventilated with big windows looking over the gardens The more expensive rooms are on the second floor and here the colour scheme is green and gold Large windows lead from each room to a wide shady verandah that runs the length of this floor There are three operating theatres, three large labour and delivery wards, consulting rooms, and an out-patient department where patients may attend three times weekly The administration rooms, the staff dining-rooms, and the all electric kitchens are on the ground floor

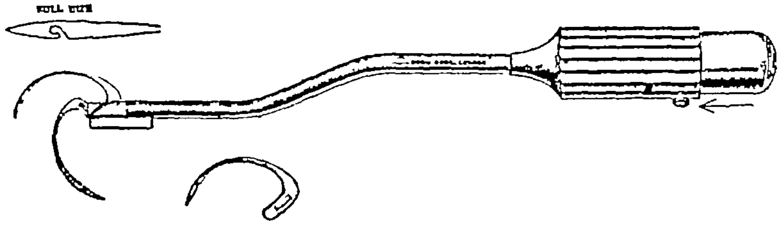
The total number of beds in the hospital is 130, of which 50 are reserved for non-paying patients, there are 80 to 100 cots About 2000 babies are born yearly, and many gynæcological cases are also treated Neither money nor trouble has been spared in making the equipment and arrangements as good as they can be made and Madame Venizelos has provided funds to maintain the hospital during its first few years The head of the medical staff is Prof N Louros, who holds the chair of obstetrics at the University of Athens

A school for midwives, founded by Madame Schilizzi, the mother of Madame Venizelos, is attached to the hospital, and the matron is also superintendent of the school It accommodates 40 to 50 student midwives, and provides pleasant living quarters for the nursing staff of the hospital The students receive a three years' training, and on qualification they return to their homes in the provinces to spread the principles of hygiene among the people

NEW INVENTIONS

IMPROVED NEEDLE-HOLDER FOR PROSTATECTOMY

The widespread performance and success of Harris's operation for suprapubic removal of the prostate necessitates a periodic review and possible alteration of the armamentarium Two criticisms of the needle-holder appear to be justified In the first place, the fact that the shaft is straight causes the operator's hand to obscure the operative field and to make it difficult to place the catgut in the appointed slot, especially if the operation is complicated by an adipose abdominal wall or narrow pelvis The second difficulty is that the actual insertion of the needle may induce bleeding Harris states that "in order to avoid hæmorrhage from the needle puncture it is important that the needle should not have a terminal sharp cutting edge The needle should be sharpened only at the actual point It is made of rustless steel, and must be kept sharp" I do not consider that this precaution goes far enough The needle commonly supplied with the Harris needle holder is flattened from side to side, and although there is no cutting edge, a slit like opening is produced which may induce hæmorrhage when the needle is inserted



In an attempt to obviate these two difficulties I have designed a needle holder which has two main characteristics The shaft is angled about half way between the needle and the holder This permits a clear view of the needle both at the moment of insertion and immediately afterwards, by keeping the operator's hand out of the line of vision The angle involves the pilot being made with a series of joints similar to a chain so as to pass the bend Secondly, a round bodied needle is provided In order to eliminate the occasional annoyance of the catgut slipping out of the slot before being drawn through the tissues, a lateral slot that renders this accident impossible is provided with the round bodied needle

I have now used this needle holder in many cases and have found it very satisfactory The angled shaft permits a good view of the depth of the wound and the round bodied needle causes no additional hæmorrhage Finally, the needle appears to bite readily into relatively tough tissue

The needle holder was made for me by Messrs Down Bros, Ltd, 22A Cavendish-square, W 1, who also suggested the lateral suture holding slot

REVIEWS AND NOTICES OF BOOKS

Methodik der Hormonforschung

Vol I By Dr Phil Christian Bomskov Leipzig: Georg Thieme 1937 Pp 716 RM.50

The first volume of this work deals with general laboratory methods and with the hormones of the thyroid parathyroid adrenal cortex and medulla and the pancreas. It is remarkable for the detail in which it describes all the working methods which may be used in the chemical and biological investigation of hormones and in particular of their assay Thus the subjects included in the 142 pages of the General Part range from a description of necessary surgical instruments and general operative methods to electrometric measurements of *p*H whilst the theoretical side is not forgotten and there are pages on the principles of biological assay and the mathematics of dose response curves, with a welcome emphasis on the necessity of basing all biological assays on comparison with standard preparations and international units In the Special Part the matter is arranged under the headings of surgical histological biological, pharmacological and chemical methods and the treatment is so full and inclusive that, whether the subject be the preparation of thyroglobulin or the assay of adrenal cortex extracts any method of repute is described in sufficient detail *for it to be carried out by a competent worker*

It is too often true of a work of this compilatory character that it is uncritical—in some respects it must be where the subject is controversial and the author must keep a judicial attitude while the case is still being argued—but here this conclusion would be unjust for the author has a sufficiently wide first hand knowledge to be able to indicate clearly and authoritatively the advantages and disadvantages of any method and its sphere of usefulness and limitations The author intends the book for chemists and physiological chemists for the medical man engaged in scientific work and for the clinician It does in fact combine chemical and biological information in just the way to be useful to all those laboratory workers in endocrinology who primarily trained in one or other science find themselves in this subject working on the frontiers between them For any type of worker whether purely scientific or technical it is a mine of information which can save the labour of many references to the original literature

A Synopsis of Hygiene

Fifth edition By W W Jameson M.A M D., F R.C.P D P H Professor of Public Health London University and Director of Public Health Division London School of Hygiene and Tropical Medicine and C S Parkinson D S O M R.C S D P H Lieut -Colonel R.A.M C (Ret) Assistant Director London School of Hygiene London: J and A Churchill Ltd 1936 Pp 623 21s

A fresh edition of this well known text-book was called for because of the mass of new public health legislation passed in the present year and the opportunity has been seized for revising much of the text and bringing the synopsis fully up to date in science as well as in law The title of this book aptly describes its purport and the positions held by the authors and their collaborators guarantee it as a sound exposition of British public health science practice and tradition The main appeal of the book is to students for the D P H course and to entrants to the various branches of public medical practice but experienced practitioners may refer to it for details which they are apt to forget It is designed to give under each section as much as every *medical officer of health is expected to know* and nothing in the non medical field which he need not know it does not profess to deal fully with the strictly medical duties of health officers. But it leaves no subject untouched and is a true and full synopsis of preventive medicine

Despite the condensation of the material the book is agreeable to read and it is remarkably free from errors Indeed we have noticed only one mis statement—namely Every five years the M O H must issue a survey report Survey reports are required only when the Ministry of Health calls for them the last call was in 1930 none was required for 1935 The index is good the references at the end of each paragraph are valuable This is a thoroughly sound *and useful book which should find a place in the* current library of every public health practitioner

Textbook of Pathology

Sixth edition By W G MacCallum Professor of Pathology and Bacteriology Johns Hopkins University Baltimore Philadelphia and London W B Saunders Co Ltd 1936 Pp 1277 42s

The fact that MacCallum s text book is enjoying its twentieth anniversary is sufficient proof of its continued usefulness and popularity Like its predecessors the present edition is arranged on an ætiological classification and not on the conventional system of organ headings The method has its advantages particularly in giving the student a better concept of disease as a process and in avoiding any tendency to turn morbid anatomy into a series of pots On the other hand it has the disadvantage that in the present state of our knowledge many diseases cannot be so classified and this makes the book less easy for quick reference the index is *however sufficiently* good for this disadvantage to be minimal

Although the general lay-out of the book is the same there have been numerous additions and alterations; in fact few of its 75 chapters have survived unchanged whilst several new ones have been added The additions have filled in the omissions we noted in the last edition and include newly described conditions such as healed pyelonephritis in children monocytic leukæmia von Gierk s disease and granulosa-cell tumour Naturally the size of the book has increased a little but with the 66 extra pages the reader gets 45 new illustrations The new edition can be confidently recommended for its up to-date information on all branches of pathology As a work of reference it should be no less useful.

Theory and Practice of Psychiatry

By William S Sadler M.D London: Henry Kimpton 1936 Pp 1231 42s

The author of this enormous book holds as he says in his preface that there is a dearth of practical literature dealing with the non psychotic groups of mental disorder and he attributes this dearth to a bias towards an institutional conception of psychiatry on the part of those who have written the accepted text-books His work is designed to make good the omission and is addressed not only to psychiatrists but to all physicians, sociologists, psychobiologists, and other trained men and women (clergymen, nurses, &c) who may be desirous of doing something, directly or indirectly, in the fields of preventive and curative psychiatry The work is divided into five parts The first deals with general principles and the second with personality problems these make up a third of the book The neuroses occupy the twenty-three chapters of Part 3, in Part 4 (134 pages) the psychoses are described, and the last part (244 pages) is devoted to psychotherapy

Numerous books have been written by psychotherapists for the same reasons as prompted Dr Sadler His own book is well intentioned, anything but abstruse, attractive for many people in its emphasis upon the value of religious and similar ideals, and its almost pastoral psychotherapy It is based on the long experience of its author as director of the Chicago Institute of Research and Diagnosis, a clinic for the treatment of paying patients, it is, moreover, fortified by references to books and articles dealing more authoritatively with some of the topics raised But the customary faults of such literature are here more than usually conspicuous It is diffuse, neither learned nor penetrating Commonplace reflections on the world and human nature are set down—either plain or translated into technical terms—as important psychological principles, while many of the crucial problems of morbid psychology are ignored Psychiatry as a whole is treated inadequately

Favourite Prescriptions

By Various Authors Edited by Sir HUMPHRY ROLLESTON, Bart, G C V O, K C B, F R C P, and ALAN A MONCRIEFF, M D, F R C.P London Eyre and Spottiswoode 1936 Pp 227 10s 6d

WHILST the older generation of physicians deplores the fact that the art of elegant prescribing is moribund, the younger replies that, when a specific remedy is known, there is no need to prescribe a blunderbuss The general practitioner, whose contact with the sick is more intimate than that of any physician, will probably think that the prescriber is more important than the prescription Whatever the truth, the compiler of a hospital pharmacopœia has to consider not only simplicity and elegance but also, and above all, economy This book contains 18 articles originally published in the *Practitioner* Each of the first 17 discusses the pharmacopœia of one of the great general or special hospitals and is written by a member of its staff The final article, by Dr L Lewis Lilley, gives an account of the National Health Formulary The reader, who should find herein much to interest and amuse him, may wonder if some of the old remedies which survive do so for any other reason than that they are sentimentally associated with the name of a famous figure in hospital medicine Incidentally he may wonder who "Uncle Henry" was, this being the name used affectionately by East End patients to connote the uncoated pil colocynth c̄ hyosc B.P Another point of interest among many is the fact that Guy's Hospital consumes some 2000 gallons yearly of liquid paraffin whereas St Mary's makes shift with a mere 330 gallons It may also be noted that most of the pharmacopœias now include some method of giving iron in massive doses in a compact form so that the patient is no longer compelled to swallow vast numbers of pills daily The prize for survival among remedies must surely be awarded to salicylic acid In the Regimen Sanitatis of the eleventh century it is stated that "willow bark treated with hot vinegar dissolves warts" In the form of collod. acid salicyl it is still prescribed for the same purpose in the National Formulary There is a foreword by the senior editor and an index is appended.

The L C C Pharmacopœia

Compiled by a Departmental Committee London P S King and Son, Ltd 1936 Pp 279 1s 6d

FROM a preface contributed by the medical officer of health we learn that this pharmacopœia is the work of a departmental committee composed of members of the L C C hospital and central medical staff, assisted by eminent authorities on modern medical and pharmaceutical practice A study of the book soon confirms the expert nature of the production Two hundred and seven pages are devoted solely to drugs and formulæ Short notes are given on all the medicinal drugs and preparations of the British Pharmacopœia and the more important ones of the British Pharmaceutical Codex Unlike most hospital pharmacopœias, the B P C preparations are here given preference to formulæ which differ only in detail from those more widely known. This is an excellent step in the right direction. Drugs and preparations subject to Schedule I and Dangerous Drug restrictions bear distinguishing marks, and this help might well have been extended to drugs in Schedule IV of the Poisons List and Rules. The increasing use of parenteral injections is recognised in the long list of ampoules Sterilised water for intravenous injections is prepared in accordance with the B P 1932 The Addendum has modified its preparation, and it is unfortunate that this and many other changes were not available to the compilers Prepared ergot, the best preparation now available, is prescribed in capsules of 5 grains, no mixture containing the liquid extract has been included—a step which will be approved by all obstetricians who still prefer ergot to the isolated alkaloids Somewhat surprising is the absence of any reference to ergometrine Special L C C formulæ are more numerous in the collection of mixtures The use of liquid extracts instead of large doses of the corresponding tinctures serves economy without loss of therapeutic activity A few parochialisms however find their place Why for instance is mist magnes sulph c̄ senna included as well as the mist sennæ co of the B P ? Ammonium bromide which has lost its official status occurs in two mixtures Mist cascaræ co might have been made more palatable by using the elixir in place of the liquid extract A syrup or an elixir of ammonium mandelate would have been a welcome addition. Pills have disappeared and a comprehensive list of tablets appears in their stead Antitoxins, sera, toxins, and vaccines are adequately represented, but there is no reference to staphylococcus antitoxin. The common proprietary arsenobenzene preparations are omitted Time honoured tables, such as dentition, incubation and quarantine, methods of administration of drugs, collection of pathological specimens, urine testing, and treatment of acute poisoning are well compiled

The preface claims that at the time of its publication this pharmacopœia was the most comprehensive and up to date of its kind, and expresses a hope that it may also be found useful by medical practitioners in general Both the claim and the hope are fully justified, any practitioner would find the book a mine of useful information

THE LANCET

LONDON: SATURDAY JANUARY 16 1937

DRUG COMPOUNDING IN HOSPITALS

THE hospital population under the jurisdiction of the London County Council is a very large one since that body now controls the institutions which until six years ago were administered by twenty-six separate authorities Just as one of the objects of the amalgamation of industrial concerns otherwise known as rationalisation is economy so it should be possible to effect a saving in the cost of administration when so many hospitals are brought under the control of a central authority It may be assumed that the L C C in embarking upon the compilation and publication of a common pharmacopœia for all the institutions which it administers was actuated by the dual motives of securing uniformity of practice and economy in the drug bill and a careful examination of the book (reviewed on p 152) suggests that in the endeavour to keep the costs of the pharmaceutical departments within bounds there has been a careful avoidance of any attempt to be economical at the expense of efficiency Nor is there any desire on the part of the central authority that medical officers should be restricted to the formulas which appear in the new book thus it is expressly stated in the preface that there is no intention to interfere with the freedom of the medical staff to prescribe what they consider necessary or desirable

A question which naturally occurs to the mind is whether the publication of a pharmacopœia for the use of all the hospitals under the juris diction of the L C C may be taken as a token that at some future time a central manufacturing laboratory may be established for the purpose of supplying all the units not only with approved formulas but also with compounded drugs As is commonly known a central buying department for the L.C C. institutions has been in existence for some time and it may be that the idea or the practicability of an extension of the principle of central buying to central production is in the minds of some members of the council. It may be recalled that a scheme for a coöperative arrangement between the London voluntary hospitals was advocated some years ago for some reason however it did not reach the stage of activity which its promoters had desired But whatever the future plans of the L C C may be the publication of their pharmacopœia is a commendable under taking It is a practical book containing abundant evidence of having been prepared by practical men and being the latest hospital pharmacopœia it should give valuable hints to those whose duty it is from time to time to revise other pharma copœias Excellent material for such a revision is provided in the annotated collection of hospital pharmacopœias just issued under the hand of Sir HUMPHRY ROLLESTON and Dr MONCRIEFF (see p 152) Very wisely the compilers of the L.C C volume have employed the British Pharma copœia and the British Pharmaceutical Codex as a basis for their work. Unfortunately the book was in the press when the Addendum 1936 was published so that no recourse was possible to the formulas and amended monographs in it that however is a matter which can and indeed should, be corrected by a short supplement

The recognition in these volumes of the vital importance of drug compounding makes it all the more desirable to bring the nomenclature of the pharmaceutical branch of hospital practice into conformity with modern usage the dispensary in future should be known as the pharmaceutical department and the dispensing chemist as the pharmacist At last week s meeting of the council of the Pharmaceutical Society it was officially stated that the Post Office had on representation being made to it agreed to discontinue the use of the term dispenser or dispensing chemist for certain appointments and to substitute the description pharmacist At the same meeting the secretary of the Society was instructed to com municate with the British Hospitals Association in respect of the voluntary hospitals and with the Ministry of Health in respect of institutions under the control of local authorities with a view to the adoption of the same policy Pharmacist ' is a statutory title and there seems to be no reason why it should not be uniformly employed

SURVIVAL AFTER RADIUM

IN their seventh annual report published this week the National Radium Trust and Radium Commission include an analysis of results obtained at their associated hospitals in the treatment of cancer at certain sites The first fact to be noted about the figures is that the proportion of patients who die from unknown causes is rapidly falling and few are nowadays lost sight of—only 3 0 per cent of those who came for treatment in the years 1930 32 As Dr BRADFORD HILL points out in his article this week on medical statistics completeness of this kind is vitally necessary for accurate assessment of the results of any form of treatment and it is encouraging to note the importance here attached to the energetic work of the follow up departments The period covered by the report is 1930–32 and the records of 5840 patients are analysed The sites studied are five (breast cervix lip tongue and floor of the mouth) and the customary test of success is applied—namely the survival rate or as it is here termed the net survival rate defined as

> the proportion of patients who are alive irrespec tive of the presence or absence of active disease to the total number of patients treated, including those who have died of operation but deducting from the total number patients dead from other causes than cancer and patients lost sight of

In addition a new measure has been introduced termed the symptom free rate and denoting the proportion of patients who have remained free from symptoms for a given period after the begin ning of treatment The argument in favour of this rate is that it may enable the success or failure of a method to be judged sooner than can be done when the survival rate is used For instance, with experience it might be possible from the trend of the symptom free rate in the three-year period to estimate the survival rate at the end of five years At present the volume of material does not suffice for such a purpose, nor indeed to show whether the two rates are in fact more highly correlated than the two survival rates at the same points of time

In reviewing so detailed an inquiry we can attempt only brief and selective reference to the results It appears that 70 per cent of the women with carcinoma of the breast who presented themselves for treatment in Stage I of the disease survived three years, and 50 per cent five years Of those in Stage III, on the other hand, only 18 8 and 13 6 per cent were alive, many of these being given only palliative treatment The 2058 patients with carcinoma of the cervix were divided into four stages of those in the earliest group 61 1 per cent survived three years and 49 4 per cent five years, whereas of those in the latest group only 12 6 per cent were alive after three years and 7 2 per cent after five Figures for carcinoma of the lip show, as might be expected, the great importance of involvement of the glands Of those in whom the growth was limited to the lip slightly more than three quarters lived five years , of those with the regional lymph glands affected less than a third survived as long Whatever the stage of disease, the outlook with carcinoma of the tongue is depressing, for of the patients most favourably placed only a quarter are alive at the end of five years, while out of 30 advanced cases only 1 remained The floor of the mouth gives less unsatisfactory results than this—at least when the glands are not involved —for rather more than half the patients lived five years With each of these sites, as has been shown over and over again, the chances of survival are better, often much better, if local spread or metastasis has not taken place Yet the report shows that the proportion of patients in whom the disease is still localised to its original site when application for treatment is made, amounts, for all the sites investigated, to only 25 per cent This figure varied but little between 1930 and 1932, although there was reason to think that the proportion coming for radium treatment at an early stage was increasing slowly among those with carcinoma of the lip, tongue, and cervix uteri Younger patients with the latter or with carcinoma of the breast to some extent tend to seek treatment at an earlier stage then those who are older The question of age is also studied in relation to survival, in two groups, under and over fifty years For carcinoma of the breast there is no significant difference though the figures suggest a slightly more favourable issue in Stages I and II with the older patients For the cervix this difference is definite and gives statistical support to the belief held by many clinicians that the prognosis is rather worse in young patients For the remaining sites the data are insufficient for investigation of any relationship between age and survival For these, too, any study of the relative success of different methods of treatment has had to be postponed till more material has accumulated, though those that prevail have been tabulated One very serious obstacle to such a study is the large number of different combinations of methods of treatment For instance 86 such combinations were distinguished in treatment for carcinoma of the breast, 66 for the cervix, 56 for the lip, 110 for the tongue, and 53 for the floor of the mouth Some attempts to cope with this problem have been made for the breast and the cervix Patients with carcinoma of the breast in Stages II and III show a slightly better three year survival rate and a higher symptom free rate when treated by interstitial irradiation combined with excision than when treated with interstitial irradiation alone, but with the smaller number of patients observed for five years there seems to be no clear advantage of one treatment over the other For carcinoma of the cervix there is a suggestion that the use of X rays combined with the Stockholm method of treatment gives a greater freedom from recurrence than the Stockholm method alone , but the survival rates at three years under the two methods show no material difference

In judging these various and numerous survival rates it must be remembered, as the report emphasises, that they give a picture of the average results of radium treatment at a very widely scattered group of hospitals, and " must not be compared lightly either with the results of special clinics, or with results based upon a picked series of cases treated by a highly skilled surgeon On the contrary, the results may be said to be those achieved by the medical skill of a large part of the country working with radium, in conjunction with other methods, upon the average cancer patient seeking treatment " The statistical treatment of the data and their presentation have, we may add, been carried out with obvious care and skill

CARBON MONOXIDE POISONING

So long as coal gas is used for heat and illumination, carbon monoxide poisoning will be of great interest and importance Dr Harvey G Beck[1] of Baltimore says that in New York only highway accidents exceed it as a cause of death We are familiar now with the way in which carbon monoxide, with its high affinity for hæmoglobin, displaces oxygen from the blood and produces a fatal anoxæmia without the usual symptoms of asphyxia Symptoms may be absent altogether, or present only as a kind of mental confusion, according to the concentration of the gas and activity of the victim This feature is at once the attraction to suicides and the trap to the accidentally exposed The struggle for air and extreme distress that we associate with suffocation are due to accumulation of carbon dioxide in the alveoli of the lungs, and there is no such accumulation in carbon monoxide poisoning Indeed the hyperpnœa that may accompany this—though almost ineffective and perhaps unnoticed at the time—actually lowers the carbon dioxide content of the blood, leading to a state of affairs which many believe to militate against recovery Administration of carbon dioxide in treatment is therefore desirable for this reason as well as for the more important reason that it stimulates the respiratory centre thereby causing deep breathing That the deep breathing so caused may be as completely effective as possible oxygen should also be given. Dr C K. **Drinker** of Boston strongly advocates and points out the advantages of a mixture of 7 per cent carbon dioxide and 93 per cent oxygen. His article is one of the clearest summaries of the physiological and therapeutic aspects of carbon monoxide poisoning that we have seen and is well worth reading

---

[1] *J Amer med Ass* Sept. 26th 1936 p 1025

Chronic carbon monoxide poisoning is a recurring subject of controversy largely as the recent advisory committee of the Royal College of Physicians of London on domestic heating by gas suggest,[3] because of confusion in terminology **Drinker** points out that acute poisoning followed by recovery may leave residual lesions The body has been deprived of oxygen and some parts of it notably the nervous system may have suffered irreparable damage He states and produces evidence that this is rarer than one would expect Acute poisoning is usually followed either by death or complete recovery but some cases do show sequelæ. This however is not chronic carbon monoxide poisoning By chronic is meant the result of continual exposure to concentrations of the gas insufficient to produce acute poisoning and chronic poisoning in this sense is the entity which is denied existence by some but in which others believe The advisory committee of the Royal College of Physicians to which we have just referred hold that the available evidence is unconvincing as to the occurrence of any definite group of symptoms which would indicate a chronic form of carbon monoxide poisoning **Beck** says The results establish the fact that slow carbon monoxide asphyxiation (anoxæmia) produces a definite clinicopathologic entity despite views held to the contrary At first sight these two statements appear irreconcilable but a perusal of **Beck** s paper leaves us with the impression that his patients whose intermittent exposure ranged from several months to eighteen years might have been suffering from repeated attacks of slight acute poisoning Common sense at least suggests that such a sequence of attacks might well have permanent results and that the possibility of their occurrence (e g in industry) should be minimised Such an entity if established would probably be known as chronic carbon monoxide poisoning in spite of definitions excluding it from that title

Chronic poisoning in the sense in which we have defined it as something gradually appearing in the complete absence of any signs of acute poisoning probably does not exist This point is not as may at first appear merely academic Dr J S **Owens**[4] for instance in the course of a paper on carbon monoxide poisoning from motor-car fumes mentioned in 1933 the possibility that low concentrations of CO may be injurious when breathed for long periods while M. **Loeper**[5] and his colleagues in Paris have just published a paper on occupational CO poisoning in which they attribute various quite severe symptoms to minute but abnormal blood CO values only measurable by a certain chemical method more delicate than spectroscopy In this group of patients long exposure to small concentrations of CO was established The argument convincing at first is not helped by the paper immediately following in which they describe l oxycarbonémie endogène This deals with a group of patients with various clinical syndromes in which similar concentrations of CO in the blood are attributed to the effects of the malady itself and not to exposure to CO Fortunately it is now generally admitted that carbon monoxide is chemically non toxic and can be injurious only in so far as it produces anoxæmia There is no evidence that exposure which does not result in anoxæmia has the slightest effect and even **Beck** s contention that repeated anoxæmia is injurious is by no means generally accepted Dr **Esther Killick** s recent work[6] is also reassuring for it shows that the body on repeated exposure to carbon monoxide develops a resistance to it so that the blood takes up less and less on successive occasions Though it may be an insidious enemy carbon monoxide has no hidden resources and can be fought very successfully if we make full use of our ordinary weapons

Dr A. Hugh Thompson consulting surgeon to the Western Ophthalmic Hospital and a valued contributor to **The Lancet** died on Jan 11th at his home in Ellerdale road, Hampstead in his 78th year

The Dublin Fever Hospital.—On Jan 1st the new constitution of Cork-street Fever Hospital became effective and the institution will in future be known as the Dublin Fever Hospital. Hitherto the hospital which has been in existence for more than a hundred years has been a voluntary institution controlled by a board of voluntary governors It was founded originally mainly by members of the Society of Friends, and there has always been a strong element of that philanthropic society interested in its management the same family names recur again and again in the roll of governors From the beginning of this year the voluntary character of the institution disappears and the hospital becomes a public one the cost of maintenance being a joint charge on the corporation of Dublin and on the Dublin board of assistance The control will be in the hands of representatives of these two bodies and of the existing board of governors of the hospital, who are constituted a perpetual college of electors for the election of such representatives The medical officers of health for the city and the county of Dublin will have certain advisory duties in regard to the hospital The present site is not sufficient for the enlargement required and it is understood that search is being made for a [illegible] and convenient site

ANNOTATIONS

HOSPITAL UNITY AT OXFORD

OXFORD will soon have lost the remains of her reputation as a home of lost causes A pioneer in the hospital contributory scheme 17 years ago, she has now started a plan for the better coördinating of hospital services comparable to the one in operation at Manchester[1] The Oxford and District Joint Hospitals Board, upon which the University, local public health authorities, and medical organisations are all represented, has been formed under Lord Nuffield as president The primary function of the Board will be to make and keep continuous touch between the various hospitals in the area, the representatives of which will thus be able to confer often upon questions of local hospital service One immediate and valuable effect of such liaison might be that cases which could not be admitted to one hospital, because all its beds were full, might be admitted without undue waste of time and money to another hospital not far away The Board further suggests that appeals for contributions, at present circulated by each hospital separately, should be coördinated, thus saving expense and avoiding overlapping Provided that subscribers may earmark their subscriptions for a particular hospital if they so wish, the Board thinks that such coördination would lead to an increase rather than a decrease of contributions Though it must be clearly understood that the Board will in no wise attempt to tamper with the actual administration of any of the hospitals, all of which will retain their identity and independence, it is hoped that, through their representatives on the Board, the hospitals will jointly consider schemes for hospital extension or the building of new hospitals suitable for the needs of the whole area Further matters that might in the future be considered by the Board are the supplementing of present ambulance services and the provision of further facilities for convalescent treatment More immediately, the Board has decided to coöperate in raising funds for the Banbury Hospital rebuilding scheme Whether or no the voluntary hospital system itself is to be looked upon as a lost cause, it still has many staunch friends, and the best way in which they can help it to survive is to make it coöperate rather than conflict with municipal services The Oxford and District Joint Hospitals Board is a step in the right direction and it seems likely that this attempt to secure local hospital unity will not long be confined to Manchester and Oxford

MASKS AND FACES

WHEN our daily colleague grows a beard or our wife bobs her hair it is bound to be disturbing for a while to our companionship There is no question as to whether the new style is better or worse than the old, what upsets us is the fact of alteration, for nothing distracts us from the realities of life so much as chops and changes in its superficialities Regular meals, a permanent Bradshaw, our own bed and old companions make for a free spirit which can go more easily and on better excursions if there is no disturbance in its temporal surroundings, the real artist of the spirit is generally a steady family man of pretty fixed habits who cannot waste his capacity for adventure on wearing strange clothes and living a curious life So there is bound to be some emotional upset when one of the great English weeklies dresses up in new clothes, with as it happens a little lipstick thrown in No one, except perhaps the printer, has thought of the *British Medical Journal* as a delicious example of typography, nor fondled its leaves with the affection of a bibliophile We have known it and loved it as a faithful source of information and inspiration, we wanted to listen to its talk, and never thought whether the familiar face we liked so well was handsome or ugly The *Practitioner* and the *Medical Press and Circular* have also had a new outfit for Coronation year, and *Nature* not long since reformed its appearance To readers and to writers it is all rather upsetting But they are not the only people who are in fact concerned The artistry of legible type and the technique of printing have devotees who are equally anxious for progress, and have equivalent progress to exploit, and if the new form is easier to read by so much will it make it easier for the reader to suck up advantage And it will not be long before the new form becomes the familiar face It reminds us of the kindly lady who looking at the memorial plaque of her husband which was just a fiasco said, "Oh, well, of course it isn't a bit like him but people will soon believe that he was like it, so its all right" And so in the end we should be equally disturbed if the beard came off or the hair went back to a bun

A SURGICAL ATTACK ON PSYCHOSES

THERE is at present no sign that timidity or conservatism is holding up any advance in the treatment of mental disorder Prof Moniz, well known for his valuable and audacious work on cerebral angiography, shows himself equally bold in attacking the problems of psychiatry He decided, on theoretical grounds, to see what would be the effect of destroying tissues of the prefrontal region in each cerebral hemisphere of insane patients His theoretical grounds, as presented here in detail, seem crudely neurological, naive, and faulty from the psychiatrist's point of view, but that is not an important objection if the procedure so based leads to striking benefit Prof Moniz modestly puts forward the opinion, shared by his distinguished Lisbon colleagues that striking benefit has in fact followed the operation in most of the twenty cases so far treated He gives full details of these cases—in which excitement and anxiety were the prominent clinical features—to enable the reader to form an independent opinion It is evident that in some of his patients the mental disorder cleared up surprisingly soon after operation and there is no reason to dispute his provisional figures—viz seven patients recovered, seven considerably improved, and six unchanged (of whom five were schizophrenics)[1] Ten of the twenty patients were treated by injections of alcohol into the centrum ovale ten by gouging out the tissue with a specially devised leucotome Prof Moniz, in his excellent account of what he did and what happened afterwards, proves his point that the operation has not had fatal or disconcerting effects, but he scarcely convinces the reader that it does more good than less heroic forms of treatment might He is however so cautious, and even deprecating, in his gentle yet persuasive claims that others are sure to try the method and, if they follow his recommendaion to reserve it for prolonged depressive attacks uicidal conditions and severe anxiety they are also ure to obtain many recoveries which will not be ecisive as to its value In the meanwhile the mono raph adds a curious chapter to the history of sychiatric treatment and yields valuable information n what human beings can stand (e g in some nstances the alcohol was squirted in while the patient ras conscious) and on the general, neurological, and sychical effects of this trauma in the frontal lobes f the brain

DUPUYTREN'S CONTRACTURE

Fourstein[1] suffered from Dupuytren's contracture n the ring finger of his left hand which was bent t 20 Having little confidence in surgical measures o decided to treat himself with radium—though he ould find little to encourage him in what had been ritten on the subject He divided the Y-shaped hickening of the palm into two fields one longitudinal the other transverse and to each field applied 0 mg radium filtered with brass gutta percha and auze for 48 minutes (40 mg hours) Eighteen days ater he gave a half-dose and in a further month epeated the full dose The result delighted him ain disappeared full extension of the finger became ossible and the fibrous mass diminished. Some ears later he observed the same condition beginning n the right hand in the form of a tender round subcutaneous mass the size of a pea He applied the ame treatment with equal success After a similar xperience with eight other cases he concludes that adium treatment is the method of choice for early ases though it does not give a perfect cosmetic esult Severe cases he thinks should be treated by urgery followed by radium to prevent the formation f cheloid

STAINING OF THE RETINA IN LIFE

The retina is translucent and the ophthalmoscope eveals only such lesions in it as are opaque to light. Examination by red free light is the one substantial dvance that has been made in revealing more than he ordinary ophthalmoscopic methods allow but arge groups of retinal affections such as the extensive degeneration following optic atrophy still remain invisible The possibility of revealing these by vital staining was suggested in a paper read on Jan 8th at the ophthalmological section of the Royal Society of Medicine by Mr Arnold Sorsby Dr A Elkeles Dr G W Goodhart and Dr I B Morris The difficulties in such a procedure are essentially two a dye has to be used that will pass the blood brain barrier and the dye has to be non toxic Since the experiments of Goldmann in 1913 it has been held that vital dyes do not stain the brain; in fact the clear enunciation of the blood brain barrier theory was largely due to the failure of Goldmann and subsequent observers to get such staining Ophthalmologists—e g Schnaudigel and Rados—brought forward additional evidence to this effect by their failure to stain the retina That the barrier was not as complete as these earlier observers thought has become apparent from the work of Lina Stern and her collaborators and it is now known that basic dyes do get through the barrier and stain the grey matter of the brain Recent work by Fisher on the iris and ciliary body and of Kuboki on the vessels of the choroid have added to the possibilities of vital staining in the intact animal Working on the rabbit with basic dyes Sorsby and his collaborators were able to obtain only transient staining in normal retinæ but the staining was of many hours duration if the retina was first damaged by chemical or mechanical means They demonstrated to the society a series of rabbits in which they had produced pigmentary degeneration of the retina by the intravenous injection of Septojod an iodine preparation and also a rabbit with thermal injury to one retina Such rabbits showed staining of the fundus when subjected to intravenous or intramuscular injection of light green and other dyes the depth of staining bearing a direct relationship to the degree of injury The mechanism appears to be that the normal retina can oxidise the dye to a colourless leuco base while the damaged retina has lost most of this ability Should it prove possible to apply these results clinically there seems a prospect that the pathological retina may be rendered visible No less important would be the emergence of what promises to be a method for the study of retinal metabolism

THE MOVEMENT FOR BIRTH CONTROL

The annual report of the National Birth Control Association for the year 1936–37 has reached us and provides evidence that its work has been progressive in many directions The two primary objects of the Association are (1) the provision by local authorities of advice for women whose health makes pregnancy medically undesirable; and (2) the provision of voluntary clinics for women whose circumstances are such that both public policy and their individual good demand family limitation In both cases those who oppose the spread of contraception point to a falling birth rate and to them the introduction to the report supplies a considered reply The words of Lord Dawson in the House of Lords are quoted when he said It is a fact that the smaller families of to-day have a higher proportion of fitter children and the mothers of those children are as well as and in my judgment better than those of any previous generation Similar support of the movement has been advanced by Lord Horder who has publicly stated that a sane population policy must include planned families

It seems to be generally recognised that the population of Great Britain will shortly become stationary before declining and the report of the Association holds that this is exactly the place where birth control clinics would play an important part by making parenthood easier and by reducing the mortality rates of infants and mothers That these arguments are prevailing is shown by the increasing number of medical men who support the Association and by the statement that during the year under consideration 18 new clinics have been established while 23 more maternity and child welfare authorities have decided to refer cases either to clinics whose number is increasing or to doctors in private practice Good practical work has been done by the Birth Control Investigation Committee of the Association the activities of which have been supported by grants from the Eugenics Society Under this committee Dr J R Baker working in the department of pathology Oxford University has continued his researches into the spermicidal substances which were reported in his recent book The Chemical Control of Conception[2] Dr S Zuckerman working in the department of human anatomy, Oxford University has been engaged upon a general inquiry into the factors concerned with the period of fertility in primates Among other things, he has been concerned in investigating the time of ovulation in primates, the variability of the phases of the menstrual cycle the cyclical excretion of the sex hormones, and the physiology of sexual skin swelling He has further been able to conduct a limited number of controlled matings with a view to ascertaining the limitations of the period of fertility occurring within the cycle

[1] Feurstein J G (1936) Wien klin Wschr 49 109

[2] Lancet 1936 1 161

A satisfactory financial position was reached during the year owing, apparently, to the success of a gala ballet performance the receipts from which transformed a probable deficit into a credit balance But with the development of the work for the coming year, larger support will be required, while there is proof that when a clinic is opened special donations are received , this means that if money is spent money is forthcoming All who read the report will learn how and why further financial support is necessary, and the work recorded in the report of the Association justifies the plea for substantial assistance

FATALITIES ATTRIBUTED TO NITROUS OXIDE

"LAUGHING GAS" has so long been regarded as an anæsthetic—perhaps the only one—which has no poisonous properties that attention is at once attracted by the record of fatalities attributed to its direct action It is true that plenty of deaths have followed the use of the gas , but this is bound to happen when an anæsthetic is often chosen, because it is innocuous, for patients who are gravely ill or are to undergo some especially trying operation Deaths in these circumstances have been explicable without assuming any toxic effect from the anæsthetic itself Some cardiac dilatation has indeed been put down to nitrous oxide, and the late Dudley Buxton believed it sometimes responsible for this complication The fatalities, however, now recorded[1] are in quite a different category, for in two of the three cases the operations were trivial There appears to be here no question either of asphyxia—which is of course easily caused by improper giving of nitrous oxide—or of death from surgical shock In none of the cases did post-mortem examination reveal to the naked eye any cause of death, and it was on the histological existence of damage to the cortex of the brain that the verdict is based of "death from destruction of cerebral cortex following nitrous oxide and oxygen anæsthesia" Details of the damage are given it was mainly in the deeper layers of the cortical cells , the neurones of all layers below the top were somewhat affected those of the lowest layers being wholly destroyed The parenchyma of the basal ganglia also showed severe degenerative changes, but the cells were only slightly reduced in number A fourth patient of whom a record is given recovered, although not completely after eight months of various pareses

These records are unusual and alarming Moreover, there is this difficulty in understanding the sequence of events as represented—that if the deaths and the early symptoms were due to the cerebral damage this must have started with rapidity early in the inhalation That creates a new conception of the possible effects of nitrous oxide, and will not probably be accepted forthwith solely on the histological evidence *from* patients all of whom died *many* hours after the inhalation had ceased The symptoms in two of the cases started about twenty minutes after the beginning of the inhalation, with spasm and jerking of limbs and stoppage of breathing. This was started again artificially but neither recovered consciousness, and they died 60 and 74 hours from the start, after incontinence and abolished reflexes had been noted The fourth patient, who recovered, was the only one of the series whose operation was a long one He was under the anæsthetic for an hour and a half, and the symptoms began an hour later

CHILDREN IN WINTER

WRITING on the care of children in winter, Dr Alan Moncrieff[1] recommends that they should go out daily, in any weather except fog between 11 A.M. and 1 P M to make the most of the sun Children of four and under should go to bed at 6 P M , half an hour's grace for each year of age being allowed to older children, with 8 P M as the limit for all children under thirteen The rest period, unless it can be taken in the open air, should not clash with the outing period Fresh air is essential by day and night and rooms must not be overheated, dry, or dusty By night, small restless children should wear a jersey or pullover , for the daytime Moncrieff suggests a woollen vest next the skin and woollen socks, a woollen jersey, or frock with woollen knickers for girls, and trousers for boys Bare knees are desirable indoors, but woollen pullovers to cover the whole of the legs should be worn out of doors by young children He does not object to gloves for those who feel the cold in their hands, and the most important point about footgear, he thinks, is that the soles should be waterproof Wet clothes especially wet shoes, should be changed at once and dry slippers should be kept for use at school There is much to be said for wind-resisting garments , but hats, unless the child has grown accustomed to wearing them, are unnecessary A little extra food to compensate for heat loss is needed in winter Extra fat in the form of butter—preferably butter produced in those parts of the world where the sun shines in winter—is excellent and its effect in producing acidosis has, he thinks, been exaggerated A bowl of porridge, or other cereal, enriched by cream, butter, or vitaminised margarine, makes a sound breakfast for children in winter Green vegetables, salads, fruit liver, fish, and fish-roes are all good, and extra milk, provided that it is "safe," should only be withheld from children with poor appetites With a diet generously planned on these lines added vitamins are unnecessary Ten per cent of colds are "home grown" and are amenable to treatment of ear, nose and throat surgical or otherwise The remaining 90 per cent are caught from another sufferer In Moncrieff's opinion vaccines and ultra violet radiation are useless against colds and attempts must be made to increase the child's resistance by sound feeding and avoidance of fatigue or chilling Cold baths or cold sponging all the year round may have a hardening effect Diphtheria, measles, scarlet fever, and whooping cough are all more prevalent in winter All children should be protected against diphtheria by injection in the second or third year of life Mild attacks of measles can be assured by the use of convalescent serum and scarlet fever responds well to serum treatment Whooping cough is now probably the greatest problem, though vaccine prophylaxis may yet prove a success Rickets persists as a characteristically winter ailment because cod liver oil is given in too small doses. Emulsions are dilute containing at best only 50 per cent of cod liver oil, while cod liver oil and malt may contain only 10 per cent. A child a month old requires a few drops daily of pure cod liver oil; at six months a teaspoonful daily is necessary and at a year one and a half or two teaspoonfuls. The maximum dose is required in winter and only slightly less should be given in summer if rickets is to be prevented or cured.

MYOPIA IN CHILDHOOD

THE comparative importance of heredity and environment in the genesis of myopia still gives rise to argument. The evidence published in 1867 by Hermann Cohn of Breslau made it seem that faulty environment is the usual cause of myopia in school-children and his influence did much to improve the conditions they worked under. Of late years the movement back to heredity has gained many adherents, including Steiger who based his conclusions on a study of 50 000 eyes. The latest contribution to the discussion comes from Stockholm where Dr Gunnar Nordgren[1] rivals his two predecessors in the wealth of his material. Since 1894 the Swedish school authorities have kept records of the incidence of myopia and though only 14 000 children were examined in 1895 their numbers have risen considerably being 27 000 in 1918. The first and perhaps the most striking observation that Nordgren discusses is the decline of myopia by about a third between 1894 and 1920. It may well have been a more than accidental coincidence he thinks, that far reaching reforms in school hygiene were introduced during this period. Between 1920 and 1935 however there was little reduction. In analysing the possible causes no significant relationships could be established between the frequency of myopia on the one hand and geographical factors including life in town and country on the other. Nor did myopia appear to be associated with poor physique. On the positive side was a possibly significant relationship between myopia and the general sickness rate but Nordgren hesitates—and indeed never completely recovers from his hesitation—over the inwardness of this association. His cautious verdict is that there can hardly be any doubt that both predisposition and external circumstances play a part in the origin of myopia but we have still to ask how great is the average frequency of myopia which can be traced to external factors. But later he adds: one can however probably by an unimpeachable general hygiene both in school and home limit the extent of myopia to this irreducible minimum. This agrees with our own modest conclusion a year ago[2] that with our present knowledge (or ignorance) it would be unwise to tamper with the principle on which most young myopes are now treated or to discourage efforts to secure special care for myopic children.

MERCURIAL ANTISEPTICS

WITH the title of The mechanism of inactivation of mercurial antiseptics by serum and its implications regarding the possibility of intravenous antisepsis" Smith Czarnetzky and Mudd[3] have published an excellent study of which our only criticism is that it seems somewhat belated. Their method was to determine the proportion of surviving bacteria at a series of time intervals in mixtures of diluted culture with solutions of mercuric chloride mercurochrome merthiolate and a compound said to be identical with Metaphen with and without the addition of 80 per cent of normal horse serum. In the presence of serum the concentration of mercuric chloride had to be multiplied by 300 to obtain the bactericidal effect exerted in its absence that of metaphen 400 times of mercurochrome—which was in any case by far the weakest germicide of the four—800 times and of merthiolate 14 000 times. These differences are of course due to the combination of mercury with serum protein and it is deduced from comparison of different curves of survival rates that this combination takes place faster than the reaction with bacteria which is responsible for germicidal effect. Further purely chemical experiments were undertaken to determine how much of these compounds will combine with a given quantity of serum protein and for each of them it was found that this amount was approximately 0 35 gramme as mercury per litre of serum. It was further shown that this mercury protein combination has itself scarcely a trace of bactericidal activity. No experiments are recorded in which whole blood was used in place of serum. It has been the experience of others that in this medium mercury compounds are incapacitated even further. The conclusion that these substances are unsuitable for intravenous antisepsis is therefore a very moderate one and it has been reached before by other means though perhaps not by so devastating and complete an exposure of the underlying fallacy. This might appear to be beating a dead horse but for the fact that misguided enthusiasm and ill chosen technique have led to fantastic claims being made on behalf of some of these mercury compounds within quite recent times. The authors are careful to say that their conclusions have no bearing on types of use other than intravenous injection the possible merits of mercury compounds for superficial disinfection are quite another problem.

POSITIVE AND NEGATIVE

THE ordinary man—and some say that doctors are the most ordinary of men—usually finds it hard to appreciate that the active disease he is observing is not caused by some equally active and positive noxious influence. The discoveries of the early bacteriologists undoubtedly supported this attitude of mind in that they were so often able to produce (on demand) microbes, toxins and what not out of their conjurors flasks. The conception of some negative factor as a cause of disease took a long time to be established and even now it is not always easy to revise our ideas of pathology to keep pace with the discoveries in the field of vitamin research. It is annoying to be told for instance that alcoholic polyneuritis has nothing to do with alcohol but is the result of a vitamin B deficiency. Yet this appears to be so. At all events Dr M B Strauss in the Harvard tercentenary symposium on nutrition[1] stated that patients could be cured of their neuritis by changing their diets but without restricting their whisky. It was suggested also that the so-called toxic polyneuritis of pregnancy can be cured by administering vitamin B as C W Theobald has maintained in our own columns[2] which would make it improbable that even this polyneuritis really

toxic in origin Strauss's contribution was but one of a series, almost all of which emphasise some relationship between disease and defective nutrition The symposium as a whole is a mixed bag, but it illustrates very well the trend of current thought "Deficiency" has quite displaced "toxins" in the minds of the investigators, and this is an excellent thing, for hypothetical toxins were a sterilising conception and have never provided us with a satisfactory basis for treatment, whereas proved deficiencies offer great therapeutic possibilities

HOSPITALS AND THE UNIVERSITY GRANTS COMMITTEE

THE work of the University Grants Committee provided the subject for a meeting of the University and Research Section of the Library Association on Saturday last Mr R Offor, Ph D, librarian of Leeds University, who opened the discussion, and other speakers were unanimous in their testimony to the freedom from red tape in the Committee's work They all agreed about the value of the quinquennial visits of the Committee to discuss on the spot with representatives of the universities their problems and needs It is for these reasons that friends of voluntary hospitals have looked to an extension of the powers of the Committee in the direction of giving financial assistance to the actual work of the hospitals Something of the kind seems to have been in the mind of the Scottish public health services committee in proposing a "teaching faculties grant" With the extension of opportunities for medical education in the council hospitals such a grant could however hardly be confined to voluntary hospitals, and in England it could not extend to the many voluntary hospitals which have no connexion with a medical school It must too be remembered that the University Grants Committee is concerned with the medical school rather as a part of the university than as an adjunct to a hospital Hence we think it very doubtful that the University Grants Committee will consider it within the scope of its duties to come to the financial support of voluntary hospitals None the less, those hospitals will join with the Library Association in their tribute to the Committee

HENRY TONKS

Prof Henry Tonks, who died at his house in Chelsea on Friday last, Jan 8th, was rightly famous as artist and teacher, and his first impulses in those directions were received while he was a medical man, and attached to the medical school at the London Hospital He gained the diploma of F R C S Eng in 1888, and was for a time assistant demonstrator of anatomy in the medical school of "the London" while he held house appointments at the hospital and at the Royal Free Hospital where he was for a time senior resident medical officer His first direct step from one profession to another was taken when he became lecturer on artistic anatomy at the Westminster School of Art and Prof Brown, when he moved from the Westminster to the Slade School invited Tonks to become his assistant From this time forward Tonks gave up the pursuit of medicine and devoted himself entirely to painting and its teaching In 1917 he was elected Slade professor of fine art in the University of London in succession to Prof Brown, a position which he held for thirteen years to the great advantage of those with the pursuit of their studies at heart, and to the discomfiture of any who thought either that drawing was easy or that accomplishment could be achieved in accordance with some set of precepts He was from the beginning associated with the New English Art Club, where his contributions were welcomed by a rather select group of admirers Otherwise he rarely exhibited his work, but several examples can be seen in the Tate Gallery, and in this gallery a special exhibition of his work was held last October This was a high tribute to his output and his ideals

During the war Tonks returned to medicine, doing certain surgical work abroad, and especially acting as an artist Here both his artistic and surgical qualities were displayed in a series of pictures of the victims of facial injuries who were treated at Sidcup These pastels were usually drawn in two stages, the first showing the injuries to be treated and the second the results of treatment, but occasionally Tonks's detailed knowledge of anatomy would emerge in an outline drawing for the scheme of restitution Seventy two of these pictures—69 pastels and 3 pen and ink drawings—are included in the army medical section preserved in the museum of the Royal College of Surgeons of England They form a striking testimonial to Tonks's *masterful drawing*, while the humanity of their object mitigates their terror

SUSCEPTIBILITY OF CHILDREN TO LEPROSY

Marchoux and Chorine[1] contend that children are not more susceptible to leprosy than adults, but owing to their inexperience and other circumstances of childhood are more likely to be exposed to infection This opinion they base on the analogy of rat leprosy They found that adult rats are as easily infected as new born rats by contact with leprous animals which show bacillus bearing ulcers, the infection apparently goes through the conjunctiva and attacks first Harder's gland at the inner canthus and afterwards the adjacent sublingual and submaxillary lymph glands When rat leprosy was induced by inoculating bacilli into the skin it was noted that the speed and severity of the infection increased with the dose of organisms and the size of the area over which they were distributed It is concluded therefore that the apparently increased susceptibility of children to Hansen's organism is due to their greater exposure, and the greater likelihood of infection entering over a large skin surface because of their close contact, naked, with their infectious parents

The question arises, however, how far it is justifiable to argue from rat leprosy to human leprosy True the two diseases resemble each other in some respects Hansen's bacillus and Stefansky's bacillus are similar in morphology and staining reactions, both are difficult or impossible to cultivate in vitro, and progressive disease has been produced by each in only one genus But the most characteristic feature of human leprosy is the *affinity of B lepræ* for the peripheral nerves and this is apparently absent in rat leprosy The contention that children are not more susceptible to leprosy than adults is not borne out by the leprolin test, which (there is good reason to believe) gives a delicate indication of the protective response of the human skin to invasion by Hansen's bacilli Compared with that of adults the skin of children reacts much less to intradermal injection of a sterilised suspension of leproma, and this variation of reaction probably has an important bearing on resistance in early and later life

PRINCIPLES OF MEDICAL STATISTICS

III.—PRESENTATION OF STATISTICS

In dealing with a series of observations the first object must be to express them in some simple form which will permit, directly or by means of further calculations, conclusions to be drawn. The publication, for instance, of a long series of case results is not particularly helpful (beyond providing material for interested persons to work upon), for it is impossible to detect from the unsorted mass of raw material relationships between the various factors at issue. The worker must first consider the questions which he believes the material is capable of answering and then determine the form of presentation which brings out the true answers most clearly. For instance, let us suppose the worker has amassed a series of after-histories of patients treated for gastric ulcer and wishes to assess the value of the treatment given, using as a measure the amount of incapacitating illness suffered in subsequent years. There will be various factors the influence of which it will be of interest to observe. Is the age or sex of the patient material to the upshot? Division of the data must be made into these categories and tables constructed to show how much subsequent illness was in fact suffered by each of these groups. Is the after-history affected by the type of treatment? A further tabulation is necessary to explore this point. And so on. The initial step must be to divide the observations into a relatively small series of groups, those in each group being considered alike in that characteristic for the purpose in hand. To take another example, in the Table showing the fatality rate from scarlet fever of hospital cases, children within each year of age up to 10 and in each five-year group from 10 to 20 are considered alike with respect to ages.

Table showing Hospital Cases of Scarlet Fever
1905–14

Fatality rate at ages

Age in years.	Number of cases	Number of deaths	Fatality rate ( )
0–	46	18	39·1
1–	383	43	11·2
–	881	50	5·7
3–	1169	60	5·1
4–	13 2	36	2·6
5–	1403	24	1
6–	1 71		1·7
7–	986	21	2·1
8–	804	0	0
9–	673	5	0·7
10–	1905	14	0·7
15 0	512	3	0·6

The fatality, or case-mortality, rate is the proportion of patients with a particular disease who die.

It is of course possible that by this grouping we are concealing differences. The fatality rate at 0–6 months may differ from the fatality rate at 6–12 months, at 12–18 months it may differ from the rate at 18–24 months. To answer that question further subdivision—if the number of cases justifies it—would be necessary. In its present form (accepting the figures of hospital cases at their face value) the grouping states that fatality declines nearly steadily with age, a conclusion which it would be impossible to draw from the 11 526 original unsorted and ungrouped records. The construction of a *frequency distribution* is the first desideratum—i.e., a table showing the frequency with which there are present individuals with some defined characteristic or characteristics.[1]

As a general rule the distribution should be drawn up on a fine basis—i.e., with a considerable number of groups, for if this basis prove too fine owing to the numbers of observations being few it is possible to double or treble the group interval by combining the groups. If, on the other hand, the original grouping is made too broad the subdivision of the groups is impossible without re-tabulating much of the material.

Statistical Tables

To return to the original table, this may be used in illustration of certain basic principles in the presentation of statistical data.

(i) The contents of the table as a whole and the items in each separate column should be clearly and fully defined. For lack of sufficient headings, or even any headings at all, many published tables are quite unintelligible to the reader without a search for clues in the text (and not always then). For instance, if the heading given on the left of the table were merely age it would not be clear whether the groups refer to years or months of life. The unit of measurement must be included.

(ii) If the table includes rates the base on which they are measured must be clearly stated—e.g., death-rate per cent, or per thousand, or per million, as the case may be (a very common omission in published tables). To know that the fatality rate is 20 is not helpful unless we know whether it is 20 in 100 patients who die (1 in 5) or 20 in 1000 (1 in 50).

(iii) Whenever possible the frequency distributions should be given in full. These are the basic data from which conclusions are being drawn and their presentation allows the reader to check the validity of the author's arguments. The publication merely of certain values descriptive of the frequency distribution—e.g., the arithmetic mean or average—severely handicaps other workers. For instance, the information that the mean age at death of patients with cancer of the lung is 51·8 years and with cancer of the stomach is 62·1 years is of very limited value in the absence of any knowledge of the distribution of ages at death in the two classes.

(iv) Rates or proportions should not be given alone without any information as to the numbers of observations upon which they are based. In presenting experimental data, and indeed nearly all statistical data, this is a fundamental rule (which, however, is constantly broken). For example, the fatality rate from small-pox in England and Wales (ratio of registered deaths to notified cases) was 42·9 per cent in 1917, while in the following year, 1918, it was only 3·2 per cent. This impressive difference becomes less convincing of a real change in virulence when we note that in 1917 there were but 7 cases notified, of whom 3 died, and in 1918 only 63, of whom 2 died.

---

[1] The choice of groups and the group-interval and the calculation of averages and other values from the distribution are discussed in numerous text-books of statistical method—e.g., Wood and Rossell: An Introduction to Medical Statistics, London: P. S. King and Son. 193

(Though the low rate of 1918 *may* mark the presence of variola minor) "It is the essence of science to disclose both the data upon which a conclusion is based and the methods by which the conclusion is attained " By giving only rates or proportions (and by omitting the actual numbers of observations or frequency distributions) we are excluding the basic data In their absence we can draw no valid conclusion whatever from, say, a comparison of two or more percentages Even when the number of observations is small, 20–25 perhaps, there is no reason why a percentage distribution or a rate should not be calculated but, as discussed later, particular care will have to be exercised in drawing conclusions

(v) Full particulars of any deliberate exclusions of observations from a collected series must be given, the reasons for and the criteria of exclusion being clearly defined For example, if it be desired to measure the success of an operation for, say, cancer of the breast, it might, from one aspect, be considered advisable to take as a measure the percentage of patients surviving at the end of 5 years *excluding those who died under the operation itself*—i e , the question asked is "what is the survival rate of patients upon whom the operation is successfully carried out ? " It is obvious that these figures are not comparable with those of observers who have included the operative mortality If the exclusion that has been made in the first case is not clearly stated, no one can necessarily deduce that there is a lack of comparability between the records of different observers, and misleading comparisons are likely to be made Similarly one worker may include among the subsequent deaths only those due to cancer and exclude unrelated deaths—e g , from accident—while another includes all deaths, irrespective of their cause Definition of the exclusions will prevent unjust comparisons

Sometimes exclusions are inevitable—e g , if in computing a survival rate some individuals have been lost sight of so that nothing is known of their fate The number of such individuals must invariably be stated and it must be considered whether the lack of knowledge extends to so many patients as to stultify conclusions For instance, if 1000 patients were originally observed, 300 are known to be dead at the end of 5 years, 690 are known to be alive, and 10 have been lost sight of this lack of knowledge cannot appreciably affect the survival rate At the best, presuming the 10 are all alive, 70 per cent survive (700 out of 1000), at the worst, presuming the 10 are all dead, 69 per cent survive (690 out of 1000) But if 300 are known to be dead, 550 are known to be alive, and 150 have been lost sight of, the upper and lower limits are 70 per cent surviving (700 out of 1000, presuming the 150 are all alive) and 55 per cent surviving (550 out of 1000 presuming the 150 are all dead) an appreciable difference To measure the survival rate on only those patients whose history is known, or, what comes to the same thing to divide the 150 into alive and dead according to the proportions of alive and dead in the 850 followed up successfully, is certainly dangerous The characteristic "lost sight of" *may* be correlated with the characteristics "alive or dead" , in other words a patient who cannot be traced may be more likely to be dead than a patient who can be traced (or vice versa), in which case the ratio of alive to dead in the untraced cases cannot be the same as the ratio in the traced cases Calculation of the possible upper rate shows at least the margin of error

Beyond these few rules it is very difficult, if not impossible, to lay down laws for the construction of tables The whole issue is the arrangement of data in a concise and easily read form In acquiring skill in the construction of tables probably the best way is, as Pearl suggests, to consider critically published tables with such questions as these in mind "What is the *purpose* of this table ? What is it *supposed* to accomplish in the mind of the reader ? wherein does its failure of attainment fall ? "[2] Study of the tables published by the professional statistician —e g , in the Registrar General's Annual Reports—will materially assist the beginner

Graphs

Even with the most lucid construction of tables such a method of presentation always gives difficulties to the reader, especially to the non statistically minded reader The presentation of the same material diagrammatically often proves a very considerable aid and has much to commend it if certain basic principles are not forgotten

(i) The sole object of a diagram is to assist the intelligence to grasp the meaning of a series of figures by means of the eye If—as is unfortunately often the case—the eye itself is merely confused by a criss cross of half a dozen, or even a dozen, lines, the sole object is defeated The criterion must be that the eye can with reasonable ease follow the movement of the various lines on the diagram from point to point and thus observe what is the change in the value of the ordinate (the vertical scale) for a

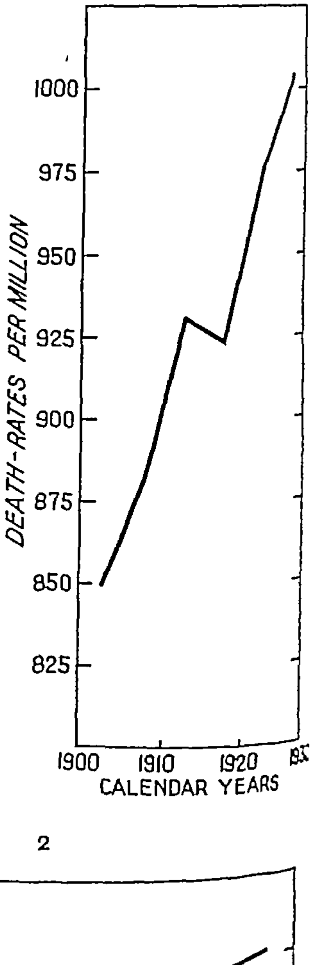
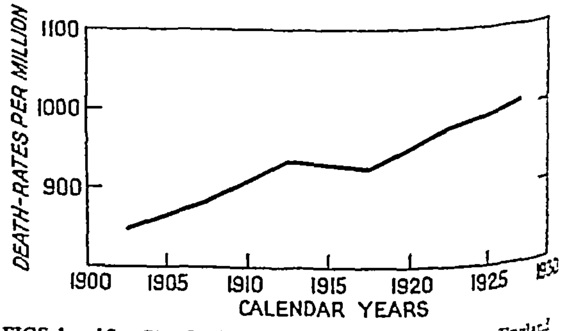
1



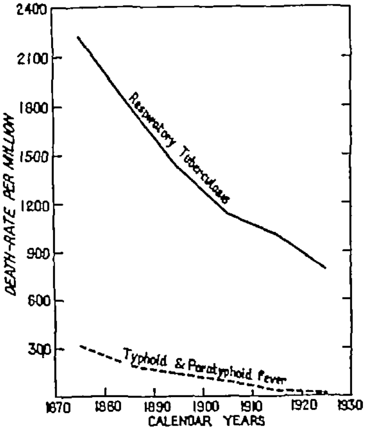
2



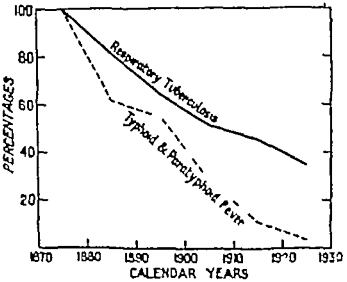
FIGS 1 and 2 —Standardised death rates from cancer in England and Wales in each quinquennium from 1901–05 to 1926–3 given change in the value of the abscissa (the horizontal scale)

(ii) The second point to bear in mind in constructing *and in reading* graphs is that by the choice of scales the same figures can be made to appear very different to the eye Figs 1 and 2 are an example Both show the same figures—namely the death rates (standardised) from cancer in England and Wales in each quinquennium between 1901 and 1930 In Fig 1 the increase in mortality that has been recorded appears at a cursory glance to be exceedingly rapid and of serious magnitude while in Fig 2 a slow and far less impressive rise is suggested The difference is, of course due to the difference in the vertical and horizontal scales In reading graphs therefore the scales must be carefully observed and the magnitude of the changes interpreted by a rough translation of the points into actual figures In drawing graphs undue exaggeration or compression of the scales must be avoided and it must be considered whether a false impression is conveyed as quite frequently happens if the vertical scale *does not start at zero but at some point* appreciably above it Graphs should always be regarded as subsidiary aids to the intelligence and *not* as the evidence of associations or trends That evidence must be largely drawn from the statistical tables themselves It follows that graphs should never be a *substitute* for statistical tables An entirely deaf ear should be turned to such editorial pleading as this if we print the graphs would it not be possible to take some of the tables for granted? Having given a sample of the process by which you arrive at the graph is it necessary in each case to reproduce the steps? The retort to this request is that statistical tables are *not* a step to a diagram they are the basic data Without these basic data the reader cannot adequately consider the validity of the author's deductions and he cannot do any further analysis of the data if he should wish without laboriously and inaccurately endeavouring to translate the diagram back into the statistics from which it was originally constructed (and few tasks are more irritating)

3



4



FIGS. 3 and 4.—Standardised death rates from (a) respiratory tuberculosis and (b) typhoid and paratyphoid fever in England and Wales In Fig 4 the rate from each disease in each decade is expressed as a percentage of the corresponding rate in 1871–80

The problem of scale illustrated in Figs 1 and 2 *is also an important factor in the comparison of* trend lines Fig 3 shows the trend of the death rates from respiratory tuberculosis and from typhoid fever in England and Wales from 1870 to 1930 Unless the scale of the ordinate (the vertical scale) is carefully considered the inference drawn from this *graph might well be that relatively* the mortality from respiratory tuberculosis has declined more than the mortality from typhoid fever Actually the precise reverse is the case—relatively typhoid fever has declined considerably more than respiratory tuberculosis. In 1921–30 the rate from respiratory tuberculosis was 34 per cent of the rate recorded in 1871–80 while the rate from typhoid fever was but 3·4 per cent of its earlier level *Absolutely* respiratory tuberculosis shows the greater improvement (from 2231 deaths per million in 1871–80 to 768 in 1921–30 compared with 321 and 11 for typhoid fever) but relatively typhoid fever shows the advantage If it is the relative degree of improvement that is at issue Fig 3 is insufficient For this purpose the rates in each decade may be converted into percentages based upon the rate in the first decade as is shown in Fig 4

It is a sine qua non with graphs as with tables that they form self contained units the contents of which can be grasped without reference to the text For this purpose inclusive and clearly stated headings must be given the meaning of the various lines indicated and a statement made against the ordinate and abscissa of the characteristics to which these scales refer (vide Figs 1 to 4)

Summary

For the comprehension of a series of figures tabulation is essential a diagrammatic representation (*in addition to tables but not in place of them*) is often of considerable aid Both tables and graphs must be entirely self-explanatory without reference to the text As far as possible the original observations should always be reproduced (in tabulated form showing the actual numbers belonging to each group) and not given only in the form of percentages—i e *the percentages of the total falling in each group* The exclusion of observations from the tabulated series on any grounds whatever must be stated the criterion upon which exclusion was determined clearly set out and usually the number of such exclusion stated Conclusion should be drawn *from graphs only with extreme caution and only* after careful consideration of the scales adopted

THE RELATIVE AS DONOR

CHANCES OF COMPATIBILITY

BY E E POCHIN, B Chir Camb, M R C S Eng
FORMERLY HOUSE SURGEON TO THE SURGICAL UNIT, UNIVERSITY COLLEGE HOSPITAL LONDON

Now that blood transfusion is a common event and continuous transfusions are being increasingly used, it is often necessary to summon such relatives as are healthy, willing, and available for tests of compatibility as donors In many cases the number of such relatives may be small and the husband (or wife) or a friend may offer instead It seemed of interest to calculate the probability that a relative would be compatible, and what relationship would be the most favourable Would a brother be less likely to be compatible than a son or a father, and how would they compare with the husband or other unrelated person in chances of compatibility? The results obtained are given below (Tables I and II), and details of the method of calculation follow It should be realised that the results are theoretical and not experimental

TABLE I

Percentage Chance of Suitability when the Donor is to be of the Patient's Own Blood Group

Patient s group	Donor—			
	Father or mother	Brother or sister	Son or daughter	Unrelated
	Per cent	Per cent	Per cent	Per cent
I (AB)	18	34	16	3
II (A)	66	69	66	43
III (B)	39	47	41	7
IV (O)	68	71	68	46
Average, whole population	64	67	64	41

II

Percentage Chance of Suitability when the Donor is to be of any Compatible Group

Patient s group	Father or mother	Brother or sister	Son or daughter	Unrelated
I (AB)	100	100	100	100
II (A)	95	95	95	90
III (B)	72	74	73	54
IV (O)	68	71	68	46
Average whole population	81	82	81	67

METHOD OF CALCULATION

The probability will depend upon the mechanism of inheritance of the blood groups and upon the actual frequency of the various groups in the population in question

The present calculation ignores cases in which serum of one group is found to agglutinate cells, apparently of the same or compatible group, on direct matching

Bernstein's theory of the inheritance of the blood groups (Bernstein 1924, 1925) is taken as the basis of the calculation This theory states in effect that the blood group of an individual is determined by his possession of a pair of genes, one derived from each parent while each of the genes is one of three possible types A B or R The six possible pairs are thus A + B (written AB) AA AR BB BR and RR the order of the genes in the pair being irrelevant Blood Group I consists of all who possess both an A and a B gene—i e type AB Blood Group II consists of all who possess an A but no B gene and thus includes both types AA and AR Blood Group III consists of all who possess a B but no A—i e types BB and BR Blood Group IV consisting of those who possess neither A nor B genes consists of type RR

Each parent passes on to his child one or other of his two genes Thus the children of the mating AA × BB are all AB (Group I), while the children of the mating AR × BR are AB, AR, BR and RR in equal proportions

The frequency of the various blood groups in the English population has been established (Hirszfeld 1919). It is also possible (Wiener 1934) from these frequencies, and assuming the population to be well mixed by marriage, *to separate the Group II frequency into the respective* frequencies of its two parts corresponding to AA and AR, and similarly for Group III

The actual figures obtained are as follows —

TABLE III

Group	I	AB— 3 1	per cent	of population
„	II	AA— 7 2	„	„
		AR—36 2	„	„
„	III	BB— 0 27	„	„
		BR— 6 9	„	„
„	IV	RR—46 4	„	„

Now, once it is known that a patient is, say, Group IV, it is easy to calculate the likelihood that a child is Group IV, and so compatible, assuming that a man's choice of wife is independent of her blood group Thus supposing the patient to be a Group IV man, 46 4 per cent. of all possible wives are also Group IV, and all the children of this RR × RR marriage will be RR and compatible with the patient A further 36 2 per cent of possible wives are type AR, of which match the children are equally likely to be AR (incompatible) and RR (compatible) Thus of this match, in half the possible cases (18 1 per cent) the child will be compatible Similarly the wife may rarely (6 9 per cent chance) be of type BR, of which match half the children will be compatible adding a 3 45 per cent chance of the child being compatible

The other three possible matings, with AB, AA, and BB, *contribute no RR children compatible with the RR* father Adding these probabilities of a compatible child, it is found that, corresponding to the full "100 per cent of wives" 46 4 per cent + 18 1 per cent + 3 4 per cent = 67 9 per cent of children will be compatible with a Group IV patient This argument applies equally whether the patient is a male or a female

When the patient is of Group II (or III) the calculation is longer, since it is necessary to take into account the fact that of Group II patients 17 per cent are type AA and 83 per cent are type AR, the children differing in the two cases Proceeding as before, and remembering that AA and AR bloods are identical in their agglutination reactions, and hence compatible, the figures are obtained that an AA patient has a 94 8 per cent chance of a Group II child, while an AR patient has a 60 8 per cent chance The average chance of a Group II patient having a Group II child is thus the average between 94 8 per cent and 60 8 per cent in the ratio of the frequencies of AA and AR, giving —

$$\frac{17}{100} \times 94\ 8 \text{ per cent.} + \frac{83}{100} \times 60\ 8 \text{ per cent} = 66\ 4 \text{ per cent}$$

This method of calculation is available both for children of the same group, and for children of any compatible group For a Group II patient the first calculation adds up the chances of a Group II child, the second, the chances of a Group II or IV child

For estimating the chance of compatibility of a parent, the analysis is rather similar Assuming again that mating takes place *regardless of group, the average* frequency of any particular mating can be estimated. Thus the frequency of an AB individual being 3 1 per cent, in 3 1 per cent of all matings the husband will be AB and in 3 1 per cent *of these* matings the wife will also be AB so that the AB × AB mating occurs with frequency 3 1 per cent × 3 1 per cent = 0 096 per cent Similarly the AB husband–AR wife mating has frequency 1 1 per cent as has also the AB wife–AR husband mating so that the frequency of AB × AR disregarding the sex of each parent amounts to 2 2 per cent of all matings

Now it is known what children, in what proportions, result from each mating. Thus given the group of the child, we can calculate the relative chance that it resulted from each of the possible matings. And in each possible case it is known whether one or both of its parents is of compatible group, and hence the chance that a parent is compatible.

To give an instance, suppose that the patient is of Group IV, represented by RR. An RR patient may be the child of any one of six matings. Column (a) of Table IV shows these matings, and column (b) the frequency of each as a percentage of all matings. Column (c) gives the proportion of children of each mating who are RR. Column (d), given by (b) × (c), thus gives a measure of the relative chance that the RR patient is a child of each mating. Clearly a mating all of whose offspring are RR is a more likely parentage for the RR patient than an equally frequent mating of which only a quarter of the children are RR. Column (e) expresses this chance of each origin as a percentage.

Column (f) now states the proportion of the parents who are RR and hence compatible, and (g), given by (e) × (f), is the final probability that a parent will be compatible.

TABLE IV

(a) Mating	(b) Frequency of mating	(c) Proportion of children RR.	(d) Relative chance.	(e) Absolute chance.	(f) Proportion of parents RR.	(g) Chance of compatible parent
	Per cent		Per cent	Per cent		Per cent.
1 RR × RR	21·5	1	21·5	46·5	1	46·5
2 RR × AR	33·6	½	16·8	36·5	½	18
3 RR × BR	6·4	½	3·2	6·9	½	3·5
4 BR × AR	5·0	¼	1·2	2·6	0	0
5 AR × AR	13·1	¼	3·3	7·2	0	0
6 BR × BR	0·5	¼	0·1	0·2	0	0
—	—	—	46·1	99·9	—	68·2

Thus a parent will be compatible with a Group IV patient in 68 per cent of cases. It should be noticed that this is not the same as the chance that one or other parent is compatible, which is obviously greater, since if the first parent is incompatible there is still a chance that the second may be compatible. Thus in this case it is seen from Column (a) that in rows 1, 2, and 3 *one of the two* parents is RR, the corresponding factor in Column (f) becoming 1 for these, and the total now becoming 90 per cent.

The calculation for the composite Groups II and III is performed in a manner similar to that used before for children. Thus the probabilities are obtained for AA and AR separately and then averaged appropriately.

Further, it is clear that the probability of a brother or sister proving compatible is readily obtained by almost the same method as for parents. Instead of inquiring what proportion of the two parents is compatible in each family, we inquire what proportion of the (other) children is compatible. It is to be noted that the chance of occurrence of any particular assortment of genes is unaffected by which assortments have already occurred in the family, just as the chance of a penny falling "heads" depends only on the details of the toss, and not on the results of previous tosses.

Thus in the case of an RR patient the analysis is the same as in Table IV until column (e), after which it is as Table V.

In this way all the probabilities in Tables I and II can be obtained. It is true that in any one family the *proportion of children of the various groups will not be* exactly, or even approximately, according to theoretical expectations. If the assumptions underlying the calculation are true, however, the probabilities would be confirmed by taking a large enough number of cases, and are thus the correct expectations in each particular case.

TABLE V

(a) Mating	Children	(e)	(h) Proportion of RR children	(i) Probability of compatible brother or sister
		Per cent		Per cent
1 RR × RR	RR	46·5	1	46·5
2 RR × AR	RR AR	36·5	½	18·2
3 RR × BR	RR BR	6·9	½	3·5
4 AR × BR	AB AR BR RR	2·6	¼	0·6
5 AR × AR	AA 2AR RR	7·2	¼	1·8
6 BR × BR	BB 2BR RR	0·2	¼	0·0
—	—	—	—	70·6

In the case of unrelated persons, these probabilities may legitimately be combined. Thus if the chance that such a person should be of different group from a patient is 10 per cent, the chance that three such persons should all be of different group from the patient is (10 per cent.)³ = 0·1 per cent. The same argument cannot, however, be applied to relatives. Thus if an RR patient has an incompatible brother they cannot be the children of an RR × RR mating, which gives only RR children; and for the remaining possible families the chances of a compatible brother are not so favourable, and the expectation for the next brother tested must be revised accordingly. If, on the other hand, a parent has been found to be incompatible, certain families are ruled out, but in the remainder the second parent is certain to be compatible except in the few cases in which a child is incompatible with both parents. The chance of compatibility for the second parent may thus prove to be greater.

TABLE VI

Chance of Compatibility of Second Relative

BLOOD TO BE OF PATIENT'S OWN GROUP

Donor	Parent	Brother or sister	Child
	7[illegible] per cent	46 per cent.	40 per cent

BLOOD TO BE OF ANY COMPATIBLE GROUP

Donor:	Parent.	Brother or sister	Child
	72 per cent.	44 per cent	36 per cent.

Table VI gives the chances (weighted average for all groups) for a second relative of each kind to be compatible, a first relative *of that kind* having proved incompatible.

CONCLUSIONS (SEE TABLES I AND II)

1. Of the near relatives a brother or a sister is the most likely to prove compatible as a donor, but the advantage is negligible except in the case of a Group I patient requiring a transfusion of blood of the same group.

2. When blood of the patient's own group is required the advantage of relatives over unrelated persons is large, especially in the rarer groups, I and III. Two unrelated persons are equivalent to one relative in chance of providing a donor. A relative is twice as likely to be compatible as not.

3. When blood of any compatible group is sufficient the advantage of the relative is less. One and a half unrelated persons are equivalent to one relative. A relative is four times as likely to be compatible as not, whereas an unrelated person is twice as likely to be compatible as not.

4. It is also found that if one parent has proved to be incompatible the other parent has a nearly equal chance of proving compatible (Table VI). If, however, one child has proved to be incompatible, any further child has a decreased chance of proving compatible, and the same applies for brothers and sisters. In fact, when blood of any compatible group is sufficient, if one son (or brother)

has already proved incompatible, an unrelated person is much more likely to be compatible (67 per cent as against 40 per cent) than another son (or brother)

MEDICINE AND THE LAW

Medical Certificate Signed by Unregistered Practitioner

William Mellor, of East Dulwich-road, East Dulwich, was fined £10 and 20 guineas costs on Jan 6th at Lambeth police court for offences against Section 40 of the Medical Act One summons charged him with wilfully and falsely using the title of "Doctor of Medicine," the other with wilfully and falsely using the description of "medical examiner," thereby implying that he was a registered practitioner The defendant's name was not, and never had been, on the Medical Register The offences were of some public importance since they arose in respect of a medical certificate given to an applicant for an air pilot's licence The Air Ministry requires a medical examination in such cases in order that the medical fitness of the applicant may be assessed A number of questions must be put by the medical examiner who must enter various particulars on a form The form is headed by a preliminary note stating that the medical examiner must be a registered medical practitioner with British qualifications Mellor signed in the space prescribed on the form for the signature of the medical examiner he added his qualifications as "M A., M D , B Sc , Lic Hom Med (Ind)" It was the "M D" in this list which got him into trouble In effect also he had put himself forward as a medical examiner who possessed the required British qualifications In the witness-box he stated that, when he signed the prospective pilot's application form, he had not noticed the printed words "Medical Adviser" This abstraction of mind the court was evidently unable to accept Mellor produced several framed certificates and diplomas, he said he held four degrees obtained after examinations conducted in London and Liverpool under extension arrangements with a university at Kapurthala in India and other institutions in America It is possible that the Air Ministry officials had their suspicions aroused by the over simplification of the entries made by Mellor Against "visual acuity," for instance, he had written "v good" without filling in the details which the form required

A third summons related to the name plate exhibited on the railings outside the defendant's address It contained the description "Dr Wm Mellor (India), Homœopath and Osteopath, U S A" This became the basis of a charge of having wilfully and falsely used the description of doctor thereby implying that he was registered under the Medical Act The magistrate dismissed this third summons being presumably not satisfied that Mellor had "wilfully and falsely" misdescribed himself in view of the evidence of Indian and American qualifications which the prosecution was hardly in a position to disprove The serious element in the case was the pretence of being a registered medical practitioner for the purpose of the medical certificate of an applicant's physical fitness to pilot an aeroplane The Medical Defence Union does good service to the public as well as to the medical profession in undertaking proceedings of this kind It is seldom an easy matter to obtain convictions under Section 40, where the statutory expression "wilfully and falsely" introduces technical difficulties It is not unreasonable to assume that unregistered practitioners would usually like to be taken for registered practitioners Occasionally it is true, an unregistered man, when charged under Section 40 of the Act, protests that nothing was further from his thoughts than to pretend to be a fully qualified doctor If so, as Lord Hewart hinted not long ago in the High Court, there are plenty of ways by which the unqualified man can differentiate himself in the description he adopts To call himself "doctor" is not one of them

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

EDINBURGH ROYAL INFIRMARY

THE annual report of the Edinburgh Royal Infirmary for 1936 gives interesting figures of advance during the past year There were 21,568 in patients, and of the 20,612 whose treatment had been concluded, 5536 were medical cases and 15,076 surgical. On an average there were 965 52 patients a day (including 72 children) with a length of stay of 17 14 days (on the medical side 26 04 days, and on the surgical 13 87) The death rate was 6 2 per cent, or after deducting deaths within 48 hours, 4 3 per cent Operations in the in patient theatres amounted to 11,682 There were 72,543 new out-patient cases admitted, with 379,688 attendances Motor accidents accounted for 415 admissions to the wards—an increase of 49 over the previous year—and 557 to the out-patient department Legally, the Infirmary could claim compensation for the cost of maintaining these cases, but in practice it was found that the amount received did not cover half the cost involved The managers of the hospital regretted that it had not been possible to effect any reduction in the waiting list

The work on the new maternity pavilion and nurses' home has been delayed by bad weather during the winter months, but it is hoped that these buildings will be ready for occupation by the end of 1937 Accommodation for sick nurses is being added to the new home at an extra cost of £6700 The full building scheme will cost about £500,000, of which some £300,000 has been contributed, and the managers propose shortly to make an appeal to the public for the additional £200,000 Important and far-reaching alterations are being carried out in the X ray department, new apparatus is being provided, including a very powerful tube primarily for the treatment of cancer, while the staff has been considerably increased

A cause of concern to the managers has been the growth in expenditure, amounting to £40,000 in ten years, and they earnestly appeal for new and greater subscriptions The total ordinary expenditure amounted to £169,694, an increase over the preceding year of £12 996, and the net result of the year's work showed a deficiency of £77,006 Fortunately, the sums for general purposes received by legacies and special donations amounted to £78,659, and it has thus been possible to meet all outgoings without drawing on invested income A gratifying feature has been an increase of £3759 in the amount received from the League of Subscribers The system of budgeting adopted a few years ago enables a strict control to be kept on all outgoings but extraordinary expenditure owing to works of reconstruction and alteration has again been high, amounting to over £28 000

A NEW NURSES HOME IN GLASGOW

A scheme that will be a notable city improvement by adding to the open spaces near the Cathedral and by greatly contributing to the beauty of Cathedral square was referred to at the annual New Year's meeting of the managers of Glasgow Royal Infirmary with the nursing staff The new nurses home the design for which has now appeared in the public press, is to be erected at a cost of £100 000 Tenements belonging to the Royal Infirmary and to the corporation are to be demolished while it is hoped that the small Cathedral Hall may be transferred to another site The only building then left besides the home would be Provands Lordship the oldest house in Glasgow The new home is to be H-shaped in design consisting of a centre block and wings with the ground between the wings laid out with lawns and flower beds The frontages will extend to 200 feet with side frontages of 128 feet All the bedrooms will be single and supplied with hot and cold water while there will be ample accommodation for recreation writing reading study and work rooms Automatic electric lifts will give access to all floors The construction is to be partly of light cream polished sandstone and partly of purple-grey brick

PANEL AND CONTRACT PRACTICE

The District Medical Service

A SERVICE which affects some 3000 practitioners and in some areas a not inconsiderable section of the population is obviously of importance to the profession and the public Though the appointment of a 'district medical officer under this specific designation dates from 1847 arrangements for medical attendance on the poor prevailed generally before this period Previously to the Poor Law Act of 1834 provision rested with the overseers of each parish who contracted with a local practitioner the method has its relic in the term parish doctor still occasionally used Under the 1834 Act the duty passed to the newly constituted boards of guardians who were urged by the Poor Law Commissioners to take into early consideration the appointment of medical officers The effect of legislation has been towards a centralisation of control further manifested by the Local Government Act 1929; thus before 1834 responsibility rested with 15 000 parish officers and in 1929 the responsibility was transferred from 609 boards of guardians in England to the 132 councils of county boroughs and county councils

A century ago the service seems to have been very extensive in scope and to have provided the usual form of medical attendance on a large section of the wage-earning population It was also more of a rural problem than it is to-day though the practice probably continuous with former times may still prevail under which an agricultural labourer with a large family is regarded as entitled to medical relief Increasing urbanisation has moved the centre of interest to the towns and in recent years the unfortunate effect of prolonged unemployment has especially in certain areas largely increased the numbers of those compelled to seek medical relief This variation may be illustrated by the following figures which show the number of persons (on Sept 26th 1930) per 10 000 population in receipt of poor relief—an approximate index of medical relief

Counties		County Boroughs	
Bedford	90	Coventry	116
Wilts	150	Brighton	187
Durham	717	Newcastle upon Tyne	687
Glamorgan	682	Liverpool	1068

No uniform method of providing medical attendance has prevailed The most usual method has been the appointment of local practitioners on a part time salary basis and the majority of medical relief districts are thus officered to-day In the earlier years after 1834 the appointment was frequently put up to tender a practice which was obviously undesirable and which came to be discountenanced by the Poor Law Commissioners. Salaries were fixed at the discretion of individual boards of guardians and consequently show considerable variation throughout the country In some rural districts remuneration may have remained unaltered with a dwindling population; in urban districts on the other hand especially in those with a heavy incidence of unemployment there may have been altogether insufficient adaptation to the increased demands Some authorities have latterly devised methods of correlating payment to work done The system is too well known to require elaboration; the officer appointed carries out his duties in the ordinary routine of general practice

Less frequent has been the appointment of whole time officers The first such appointment was in operation at Leighton Buzzard in 1840 but the system has not been extensively followed Such officers may devote the whole of their time to district medical duties combined perhaps with those of public vaccinator a method which prevails for instance in parts of Birmingham and West Ham in Smethwick and Middlesbrough; the major part of the work is done at central dispensaries usually attached to relief stations A criticism made of such service is its obvious relation to the Poor Law

Whole time officers again may combine the duties of district medical officer with other functions such as the charge of a public assistance institution or an appropriated hospital thus providing a wider range of interest and a linking up of in patient and out patient treatment In several districts of London the duties of district medical officer are carried out by the resident staff of L C C hospitals Again but very exceptionally the duties may be combined with those of medical officer of health to one or more district councils

THE FREE CHOICE SYSTEM

These have until recent years been the customary methods by which the work has been conducted Since the introduction of the Local Government Act 1929 this service has with other functions transferred from boards of guardians come under review by the local authorities concerned but it remains a poor law function as there exist no power under the Public Health Acts for the provision of a domiciliary medical service While the majority of authorities have continued on former lines with perhaps some adjustments others have introduced what is known as the free choice system " whereby the work is thrown open to a panel of practitioners willing to act The idea is not new, it was suggested in a memorandum submitted by the British Medical Association to the Poor Law Commissioners in 1839, and has been in operation in a small area in Kent since 1928 Its re-emergence as a policy is due primarily to the view that it would tend to minimise the association of the service with the Poor Law and it has been stimulated by the former lapse from medical benefit of many insured persons and the consequent resort of these and their families to the poor-law provision, usually involving a change of medical attendant

The system cannot be put into immediate and full operation in any area, for district medical officers have security of tenure, so that there can only be partial introduction as existing appointments fall vacant It was first introduced in Newcastle-upon Tyne in 1933, and in the same year was adopted in Wiltshire and East Ham, in 1935 it applied to 7 out of 10 medical relief districts in Newcastle upon-Tyne, to 18 out of 68 in Wiltshire, in East Ham to the whole borough except one small district Introduction to a varying extent has since taken place elsewhere as, for example, Warrington county borough, and the counties of Cambridge, Cornwall, East Suffolk, Essex, and Glamorgan The general operation of the system is much the same in all areas but there is considerable diversity in remuneration Thus, in Newcastle the payment is 5*s* per patient-quarter for short-period cases, and £1 a year for those under treatment for more than two consecutive quarters, in East Ham the rate is 16*s* per patient year, in Wiltshire it is 25*s* for each case seen during the calendar year (20*s* in one district), and here the payment covers the supply of drugs The service provides a patient with the doctor of his choice, and is thus in line with private practice and with medical benefit under the National Health Insurance Acts It is likely to be more costly than the other methods mentioned, which however have not infrequently been underpaid Its possible reaction on public assistance will be scrutinised by administrators It introduces the local authorities to a closer contact with the general body of practitioners in their areas, and this may prove a prelude to further developments

Dr J A Charles has reported[1] on the working of the system in Newcastle, it would be well if similar comprehensive reports were provided from other areas where the system has been in operation for a sufficient period so that fuller details of its working may be available for the guidance of others No medical service can in these days remain static, and this latest development in the district medical service will be watched with interest in its relation to the sick person the medical profession, and public administration

Capitation Fee for Adolescents

As we set out a fortnight ago the Ministry of Health and the Insurance Acts Committee failed to agree about the terms on which medical benefit shall be provided for young people between leaving school and reaching insurable age The I A C decided to consult representatives of local medical and panel committees about the impasse thus created and a conference was held on Jan 7th in the Great Hall at B M A House with Dr D Elliot Dickson of Lochgelly Fife in the chair Despite the prevailing epidemic a fully representative gathering was secured although the list of deputies was long The report of the I A C having been moved by Dr H C Jones the conference agreed, at the suggestion of Hastings to the discussion being conducted in private At the conclusion it was announced that the following resolutions had been passed without dissent

That the offer of the Minister of Health of a capitation fee of 7*s* 6*d* for medical attendance on insured persons under 16 years of age be rejected

That in view of the inadequacy of the existing capitation fee, and pending the result of negotiations for its increase, this conference is not prepared to accept for attendance on insured workers under 16 years of age a capitation fee less than that paid for adult insured workers

That this conference recommends insurance practitioners to decline service for the provision of medical benefit for insured workers under 16 years of age on the terms offered by the Minister of Health

That the I A C be authorised to take action in the light of the decisions reached by the conference

NON MEDICAL COMMENT

In an article entitled Views of the Doctors the *National Insurance Gazette* sets out fully the case made by the I A C, quoting almost verbatim the general statement of that committee's views summarised in our columns a fortnight ago The *Gazette* itself sees no difficulty about either of the question outstanding between the I A C and the Ministry The doctors "have complained, more or less bitterly," the *Gazette* remarks, "of the amount of clerical work thrown upon them—all of it distasteful to professional men who could spend their time in much better ways other than doing mere clerk's work The only point is that the doctors cannot be allowed to say that it is a big thing when they want paying for it, and nothing when they have to give it up" On the second point—are adolescents in need of the same amount of medical attention as the existing insured population?—the *Gazette* suggests that the reply "must be based mainly on medical and statistical knowledge", concluding, "We are interested in a fair settlement for two reasons As citizens and taxpayers we want the State to get a square deal as National Health Insurance workers we want the benefit to the school leavers to be satisfactory"

Retirement of Sir Walter Kinnear

The retirement, on Jan 1st, of Sir Walter Kinnear from the position of controller of the Insurance Department of the Ministry of Health, which he had held since 1919, deprives the public service of one of its most distinguished and popular members As a student at the Royal University of Ireland, he had a brilliant career, graduating with honours in mental and moral science, and soon became a prominent figure in the insurance world In 1911 he was appointed deputy chairman of the Irish National Health Insurance Commission, and during the later years of the war he was seconded to the English Commission His success in handling the difficult problems that beset the inception of the health insurance system both in Ireland and in England clearly showed that he would be in his right place as head of the Insurance Department of the newly constituted Ministry of Health He was not only a highly efficient and popular administrator, with the personal charm characteristic of many of his countrymen, but his thorough grasp of the principles of insurance in all their bearings made him an international authority on the subject His voice was influential at Geneva, and last year, by special request, his services were made available to the Australian Government to assist in exploring the possibilities of national insurance in Australia He carries with him into retirement the good wishes of all who were associated with him in his long and distinguished career

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations Each contributor is responsible for the section for a month his name can be seen later in the half yearly index

FROM A PUBLIC HEALTH CLINICIAN

III

This is coronation year and different coronation thoughts pass through our minds—to nearly all a procession is one of the foremost If we personally do not want to see the procession it is certain that some members of our family will so wish Granted the time I should like to see the coronation procession if that were all but there will be crowds and crowds and a very early start will be necessary unluckily it is not possible to take a seat at 11 25 for an 11 30 procession and then leave quietly Every one in their lifetime should see one great procession—mine was the funeral procession of King Edward VII The night before I had spent over 4 hours in a queue to see the lying in state at Westminster Hall and then came away disappointed Fortunately the crowd was not as the papers declared pervaded by a spirit of silent reverence, and there were many humorous incidents but it was tiring for all that, and left me determined never again to queue up for anything So next day I arose late and set off to see the procession Walking in mid road along the route the vastness of the crowds impressed me Now and again I sidled one way or the other to secure a stance but a chorus of protests moved me on Suddenly it struck me that when the procession passed the side roads would be closed so I took up a humble position at the back of the crowd at a point where a side road entered confident that when that road was closed I should be propelled willy nilly into a front place and so indeed it befell.

Passing through life one has at times similarly useful inspirations or experience suggests something that has not yet occurred to others; at the large cheap restaurants where I take my meals I have noticed that small waitresses are usually the quickest an observation that has proved time saving Another similar discovery was that if when waiting and waiting to be served in a crowded room I sat back and obviously read a large evening paper steps were soon taken to secure service It would be interesting if others would give us the advantage of similar discoveries among the smaller things of life.

* * *

Most practitioners can narrate experiences outside the routine of normal medical practice Thirty years ago when acting as locum in a Hampshire practice I had as temporary partner a wise and observant practitioner Called one day to see a blind woman in later middle age, the patient told me that during the night her husband dead some 10 years had visited her stood at the foot of the bed and conversed pleasantly She had been blind for some 15 years but averred that on this occasion she had seen her husband as clearly as she had ever seen in her best years During the afternoon I told my partner the story and he remarked She ll be dead before to morrow I asked why? The patient was ailing but there was nothing to justify such a prognosis They always die when they tell those stories was his reply

Since then my experience has confirmed that practitioner s belief An old lady 10 years a widow told me her husband had visited her and she saw him more clearly than I see you now though she had never seen him since death and was not at the time thinking of him. Within 12 hours that patient had died also and it has happened similarly with 2 other patients It is not only husbands or wives that are seen but any intimate friend or relative who is no longer alive.

Speaking to a clergyman with a far more intimate experience of dying folk than I am ever likely to acquire, he told me of several similar instances he had met with and believed that if the patient was sufficiently conscious to describe it such an experience would be found to be usual. As this is not a theological lecture I will pass over the explanations he offered; for myself I have no explanation and am left wondering My own *experience of such events* is too limited for any generalisation errors of observation or narration may have crept in I wonder

* * *

Ornithology is rather a favourite pastime for doctors with botany a close second We are speaking of course of the active minded members of the profession or would it not be more correct to say natural history minded for many if not the majority who find an alternative solace in bridge or golf have equally active minds The study of bryology and mycology meaning by that mosses and fungi is less popular and yet equal in interest to botany The mosses are difficult because a proper study entails low power microscopy but if the observer remains a dilettante as previously advised and intelligent recreation is his chief objective resort to the microscope will be seldom needed. For fungi a pocket lens should suffice but this form of life presents a field quite equal to that of botany My first discovery of *Clathrus cancellatus* a large fungus showing a wide grey network with large mesh was indeed a red letter day; and then there are various stag horn and stink horn fungi some of them bearing ancient and almost lewd latin names It is interesting also to note the varied forms of parasitism displayed and how the death of trees and other vegetation is caused The ways of nature are indeed ruthless

The difficulties of the fungus hunter are that wet weather is always best and may be essential for certain forms and that many fungi have a distinct smell sometimes a most offensive distinction My children trained in natural history methods, will stop suddenly when passing through a wood and call out stink horn somewhere near And there are others almost as bad as the stink horn The hunt for fungi is called for some reason a foray though I know not why akin perhaps to the special names—flocks drove coveys—of groups of various animals or to names given to different nests as earth dray or holt I should like to see more doctors interested in fungi

* * *

Apart from natural history history itself provides a fascinating if more sedentary hobby Gibbon s

"Declme and Fall" presents useful pabulum for a train journey, far better than most novels provided always that the reader has not already read it, as so many have done, when too young fully to appreciate the charm I read Gibbon's "Declme and Fall" for the first time in trains, and it took quite a long time I am now engaged on Grote's "History of Greece" which has not quite the same attractions and will take longer, in fact it seems possible that when death overtakes me, Grote's History will still be unfinished

The secret of enjoyment of such reading is never to read for instruction, never to regard the reading as a lesson, never to attempt to remember, but to read purely for amusement and recreation Novels and films show us life as it might be but certainly is not, history presents life as it was and still very much is Gibbon is not the only work commended, there are English histories, French histories, and period histories Then a similar field is covered by biographies which may give an interesting high power view of some special time or place

A knowledge of human nature is of the highest importance to any doctor, and his life's work presents constant opportunities for expanding his knowledge, but to know human nature one lifetime is not enough, history may assist

* * *

Archæology attracts many devotees, it used to attract me and many pilgrimages have I made to old buildings and well known churches, but to day the taste has passed, as tastes will sometimes, possibly the result of too many archæological excursions The study has its limitations and has not the attraction of natural history, but it is interesting to form conceptions of the habits and life of our ancestors disclosed by a study of their buildings and remains.

The past deserves respect and may provide lessons and examples useful to day, but if the sixteenth century had been solely devoted to the past we should have missed many of the renaissance productions which receive homage to day, and should still be admiring rush covered floors and the rather clumsy architecture of the Dark Ages Perhaps team work here, as in medicine, is best Those who feel so impelled will produce for us new forms of art and architecture while the archæologists criticise these from their knowledge of the past

---

CORRESPONDENCE

INFECTION AND DISINFECTION

To the Editor of THE LANCET

SIR,—The lecture by Sir Weldon Dalrymple-Champneys reproduced in your issue of Jan 9th will be read with interest by practitioners other than medical officers of health and should appeal to the educated layman I should like to refer to three points

First, whooping cough If it is true that the patient has already ceased to be infectious *by the time the "whoop" appears*, then many young prisoners may be liberated safely and much domestic inconvenience ended We all know that the whoop may persist long after infection has disappeared, but experience (apparently fallacious) has suggested that the early convalescent may be a source of infection Moreover, if this be correct, our present efforts at prevention are futile

The inclusion of infectious disease blocks in general hospitals is not peculiar to Scandinavia It has long been the practice in our naval hospitals without, so far as I know, any untoward results Doubtless it would have been adopted more widely were it not for the fact that local authorities provide for infectious disease and, for the most part, voluntary bodies for other sickness Nevertheless the idea is valuable on the grounds that small isolation hospitals are usually uneconomical and inefficient, and that unduly long journeys are not in the interest of the patient even under modern transport conditions

Lastly current and terminal disinfection There is no doubt that "a good spring cleaning' is all that is necessary in most diseases when the patient has been treated at home throughout his illness, but I suggest that the full ritual is desirable in the case of diphtheria patients removed to hospital while still highly infectious and when any infectious disease occurs in a boarding house or hotel In scarlet fever practice varies Admitting that infection in this disease is mainly *personal* to the sufferer, undetected cases and carriers, there still remains sufficient evidence in the opinion of many to justify full disinfection.

I am, Sir, yours faithfully,
G B PAGE,
Medical Officer of Health Exeter

Public Health Department, Exeter Jan 11th.

NASAL SINUSITIS IN CHILDHOOD

To the Editor of THE LANCET

SIR,—Your leader on this subject draws attention to a common malady but one not very familiar to those in charge of young children and school children, judging from the regular stream of cases referred to hospital for removal of tonsils and adenoids, when the underlying condition is a nasal sinusitis

Complete nasal obstruction in infants and children is most commonly associated with a nasal discharge due to a sinusitis, which is also a fertile cause of a recurrent otitis, chronic cough, and relapsing chest conditions A large mass of adenoids produces only *intermittent* nasal obstruction In my experience the mucoid nasal discharge arises more frequently from the ethmoidal cells than from the antra

Cases of nasal sinusitis may often be recognised by the presence of nodules of lymphoid tissue scattered on the posterior pharyngeal wall, visible below the level of the uvula A blob of mucus depends from the post nasal space, coming into view when the child gags In the presence of these signs, a cure of the nasal symptoms cannot be obtained by removal of tonsils and adenoids The incidence of "clinical" nasal sinusitis is certainly more common than is realised, but percentages are deceptive Anyone interested in the subject—especially if he is known to have some 'new" treatment—soon becomes inundated with cases that are referred from all quarters, with the result that an exaggerated idea is obtained as to its real prevalence

In the last five years at the Queen's Hospital for Children I have made it a routine to wash out the antra in all cases with a nasal discharge I can only recollect some half a dozen cases in which pus was washed out of the antrum (I exclude cases of complications such as orbital cellulitis secondary to an acute pan sinusitis.)

Most of the antra must have contained only watery mucus, or have been empty as the wash-outs were returned clear in spite of the X ray disclosing antra which were completely opaque This opacity must therefore indicate a thickened lining membrane only I have never observed a fluid level in the antra of children On a few occasions in the past, on clinical and radiological grounds I have explored the antrum through the canine fossa and have been disappointed by the small amount of disease disclosed—merely a slight thickening of the mucous lining of the antrum with no fluid visible The discharge must therefore have had its origin in the ethmoidal region

A difficult problem arises in considering the treatment of the chronic cases—and many become so in spite of all types of treatment

All my patients are treated as a routine with a course of nasal lavage and displacement which is performed as follows The child lies down with the head well extended over the edge of the pillow so that a line through the tip of the nose and the auditory meatus is vertical. While the child chants K K continuously a solution of normal saline (with ¼ grain of ephedrine hydrochloride added to ½ pint) is slowly dropped from a rubber bulb syringe into one nostril, while a nozzle attached to a suction apparatus applied to the other nostril draws the fluid away In this way the nasal chambers are thoroughly flushed with the solution and all adherent and tenacious secretions removed The ephedrine shrinks up the nasal mucosa and facilitates drainage from all the sinuses The symptomatic relief is instantaneous and impressive About 4–6 oz of solution is used for each nostril The treatment is repeated 2–3 times weekly for six weeks At the end of each seance 20 c.cm of solution are dropped into the nose slowly One nostril is blocked with the finger while intermittent suction is applied through the other nostril—to displace the solution into the sinuses The child s coöperation is essential I have used this treatment for the last four years and the results on the whole have been gratifying in the acute and subacute cases The chronic cases derive considerable benefit but tend to relapse when the treatment ceases

If the symptoms are not relieved antral lavage is practised under anæsthesia and the nasal displacement repeated subsequently I have been disappointed with the results of antral drainage and only after much consideration do I perform an inferior intranasal antrostomy as I consider many of these cases to be ethmoidal and not antral in origin

I am Sir yours faithfully

London W Jan 7th N ASHERSON

PURIFIED LIVER EXTRACTS

To the Editor of THE LANCET

SIR,—In your issue of Dec 26th last Dr C C Ungley describes the trial in pernicious anæmia of a preparation said to be a "further purification of Dakin and West s liver fraction He states that the further purification has been obtained by applying the process described by us in the *Acta Medica Scandinavica* The method described in his article however as used for this further purification consisted *in applying only* one part of our method to anahæmin the original Dakin and West liver fraction

In terms of the still unisolated anti anæmic pure factor the product examined by Dr Ungley must be a relatively crude one By our method of adsorption on charcoal and selective elution with phenol water and phenol we have consistently prepared direct from liver active material in very high concentration In terms of the total solids present the potency is considerably higher than that of Dr Ungley s preparation We maintain however that a mere statement of the total solid content of a liver extract is in the present state of our knowledge likely to be very misleading in our opinion, writing as chemists it may involve clinicians in serious fallacies

Our investigations indicate that the Dakin and West method leads to inconsistent results and that it also involves a considerable loss of the anti anæmic factor By adsorption on charcoal and selective elution with phenol-solutions we obtained active material at a high concentration we also found that our process gave rise to a product of remarkably constant clinical activity By repeating the process of adsorption and elution followed by other methods of purification not yet published in detail further concentration of the hæmopoietic factor could be obtained This is shown by the fact that we prepared material of such potency that 0·7 mg produced a high reticulocyte response in the hands of Strandell Poulsson, and Schartum Hansen

We wish however to insist that even after this degree of purification we had not obtained the chemically pure factor It is probable that at least two thirds of our richest material consisted of inert matter

At the present time therefore we consider it is undesirable to state the dosage of a parenteral liver extract in terms of total solids since inert substances must constitute a large proportion of the product *unless we push the purification to an advanced and* uneconomical stage If we assume that the amount of pure factor in a dose weighs 0·5 mg (which is likely to be much too high) the statement that 25 mg of solids gave a maximal response shows the dose to contain 98 per cent of inert matter and 2 per cent of the active factor We agree of course that a low total solid content is desirable but not that this gives a standard by which we can estimate dosage We can produce from a given quantity of fresh liver a product of *unvarying* potency with a *very low* total solid content by stopping our process at a given stage but the actual weight of the dose may vary by 50 or even 100 per cent

On the manufacturing scale the proper objective must be to produce in the highest practicable degree of purity an anti anæmic preparation of unvarying potency Dr Lester Smith of the Glaxo Laboratories Greenford England working in conjunction with us has now been able by this method to make such a preparation in which is produced from 100 grammes of fresh liver a fraction having an average weight of about 10 mg The material is dissolved in 2 c cm —i e at a concentration of about 5 mg per c cm. A maximal reticulocyte response occurs after the injection of a quantity of material produced from 100 g or at the most 200 g of fresh liver with a corresponding rise in the red blood corpuscles This product as is clear from its small weight is of a high degree of concentration but it is our earnest hope that the dose will not be stated in terms of its weight At the present time we rely upon the standardised method of manufacture and *the constant potency that has been found clinically* Expression of activity in terms of the weight of original fresh liver has a useful meaning only in such an instance

We understand that clinical trials of this product are being made in England (as well as in this country) and that it will be generally available before long We must apologise for trespassing on your space at such length, but we think it only fair to ourselves and our English collaborators to make it clear that the paper by Dr Ungley, except for the one step in purification described, has little reference to our own published work or to our more recent investigations

We are, Sir, yours faithfully,

CONVALESCENT SERUM IN INFLUENZA

To the Editor of THE LANCET

SIR,—On analogy with other virus diseases, such as measles, it seems reasonable to assume that serum obtained from patients convalescent from influenzal might be of therapeutic benefit The suggestion was, we believe, first put forward by Dr Herbert French in 1919, but has never been practised, at any rate on a large scale The recent researches of Laidlaw on the transmission of influenza to ferrets have shown that these creatures do in fact develop antibodies as the result of an attack This would be a strong point in favour of the use of convalescent serum were it not that after a few months of immunity they become again susceptible, even though antibodies are still in the blood. Possibly, however, protection depends in part upon these substances, and upon their degree of concentration in the body

Our purpose in writing this letter is to ask those medical men who are now dealing with influenzal patients to obtain blood from them when they are convalescent If they will send either the blood or preferably the patient to the Bacteriological Department, Guy's Hospital, a batch of mixed sera will be obtained and treatment of influenzal patients carried out with the usual controls It is hoped in this way to decide whether the serum is of any value and, if so, to aim at the collection of large supplies so that we may at last have some substance of definite therapeutic and prophylactic value to guard the population against future epidemics Will those doctors who are good enough to collaborate in this manner kindly select only those patients in whom the diagnosis of influenza was unquestionable and preferably uncomplicated ?

Blood may be collected into a sterilised vessel by any of the recognised aseptic methods of venepuncture, and the following suggestions for the collection of serum may be helpful —

If apparatus is not to hand, on receipt of a message to Hop 1654 collecting apparatus will be sent to any medical man offering to send blood This will consist of a sterilised needle and rubber connexion fitted to a sterilised 250 c cm screw-capped bottle The skin over an arm vein should be carefully cleaned, the vein distended by pressure higher up the arm and venepuncture performed in the ordinary way, the blood being run directly into the bottle When this is nearly full, the pressure on the arm is released, the needle withdrawn, a pad placed on the site of puncture and the cap screwed on to the bottle The blood should then be sent directly to this department The whole procedure must be as aseptic as possible If the patient is sent to the laboratory for blood collection, a preliminary telephone message would be appreciated

We are, Sir, yours faithfully,

BUFFER ACTION IN GASTRIC DISORDERS

To the Editor of THE LANCET

SIR,—We would like to draw the attention of English colleagues to some observations we have made on the utilisation of buffers in the treatment of gastric disorders [1]

The optimum acidity for peptic digestion ranges from pH 1 5 to about pH 4 0 , below 1 5 the stomach is liable to be attacked by its own contents, and above 4 0 pepsin ceases to act From this it may be supposed that disorders due to irregular acidity of the gastric juice will be relieved by a remedy that maintains a hydrogen ion concentration near the optimum Such a remedy, unlike the acids and alkalis usually employed, should be capable of correcting both excessive acidity and excessive alkalinity This property is possessed by the substances called buffers, which are usually mixtures of at least one salt and one acid The essential features of buffer action will be seen from the following example

An equimolar solution of acetic acid and sodium acetate has a pH of about 5 If we add some hydrochloric acid *part of the sodium acetate is converted into sodium* chloride, liberating acetic acid. The latter dissociates very little, and the number of free hydrogen ions in the mixture—i e , the acidity—is not much increased, despite the addition of the hydrochloric acid If, on the other hand, sodium hydroxide is added instead of HCl it converts some of the acetic acid into acetate, but the remaining acetic acid breaks up into ions until nearly all the hydrogen ions consumed by formation of acetate have been replaced.

In searching for a physiologically harmless buffer with a pH of about 2–3, one of us (F K) devised a mixture of sodium biphosphate (86 parts) and sodium bisulphate (14 parts), and this is now sold under the name of Optacid The buffering capacity of the mixture is far greater against acids than against alkalis , but it is right that this should be so because the contents of the stomach have to pass into the duodenum and be made alkaline for tryptic digestion.

Hitherto almost every chemical treatment of hyperacidity is based on the neutralising action of alkaline—or at most neutral—compounds But complete neutralisation of the contents of the stomach is by no means always desirable, since its effect is inhibition of peptic digestion and often an increased secretion of acid by way of compensation This defect of alkali therapy has often been pointed out. The commonly used bicarbonate of soda, magnesia usta and magnesium carbonate, are extreme representatives of their class, the pH of concentrated solutions varying between 7 and 11 (The insolubility of the magnesium compounds does not prevent suspensions of them from becoming alkaline as a test with phenolphthalein indicator will show) In recognition of this objection the alkalinity of remedies recommended has been gradually reduced. Compounds of alumina and silica with alkali came into use , but though they may do something to protect the wall of the stomach their alkalising effect is much reduced—so much so that the usual doses hardly suffice to weaken superacid gastric juice Greenwald [2] describes a mixture of calcium and magnesium phosphate which was the first remedy to weaken, but not essentially neutralise the gastric acid Even this mixture, however, is in itself neutral, and though it counters acidity it does othing to relieve subacidity Optacid is the first emedy to do both.

[2] Greenwald, I (1923) *Proc Soc exp Biol , N Y* 20, 435

The accompanying figure shows the effect of arious quantities of (1) sodium bicarbonate (2) an lum preparation and (3) optacid on the pH of xtremely acid gastric juice (from an ulcer patient) in vitro and illustrates the stability of its action

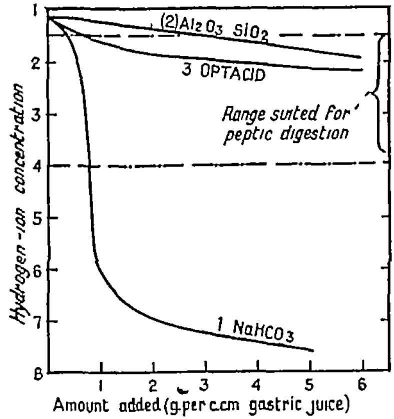

Chart showing changes in the hydrogen ion concentration of strongly acid gastric juice on addition of various quantities of (1) sodium bicarbonate (2) an alum silicate mixture and (3) optacid.

A similar advantage is gained when the juice is obtained from a stomach secreting little acid the high initial pH is quickly lowered to about 3 but no overdose will reduce it further than 1 6 Test-meals have confirmed the presumption that the ambivalent normalising action of optacid would be the same in the stomach as it is in vitro Phosphoric acid does not inhibit peptic digestion[3] the normal dose of optacid was found not to diminish the activity of trypsin in the duodenum[4] It has also been shown[1 4] that the alkali reserve of the blood is only slightly diminished by very large doses (4 grammes) of optacid, and acidosis therefore need not be feared though it is wiser not to try the new remedy in patients already acidotic (e g in severe diabetes or renal disease) Optacid acidifies the urine and the acid reaction prevents the possible formation of phosphate stones

In the treatment of gastric disorders we give optacid in tablets of one gramme or in small granules One gramme is usually taken at breakfast and two at dinner and supper Where there is much superacidity we have thought it prudent to give the medicine during or after meals while for cases with subacidity it is given a few minutes before meals The tablets are broken into a few pieces and taken in water and when more than one tablet is used an interval of ten minutes or so is allowed between them Patients with deficiency of acid usually respond to treatment within a few days but if pepsin also is absent from the juice it will have to be added Really serious affections of the mucosa (e g in pernicious anæmia) are probably outside the range of the new medicine and in very severe gastritis the neutral buffer action of mucin can only be overcome by large doses of optacid. The results with superacidity are equally satisfactory both in ulcer cases and in functional disorders Of 39 patients with peptic ulcer 7 were not benefited however in 2 of those the secretion of acid was normal and we think it likely that normal gastric acidity is sometimes sufficient to excite the damaged mucosa of a stomach, so that in these cases of peptic ulcer it may be good treatment to neutralise the gastric acid completely for a time But for the majority of ulcer patients we prefer our buffer mixture to alkalis Results obtained mainly in the internal department of the Jewish Hospital Budapest, among patients under the care of Dr L Lévy as chief physician may be summarised briefly as follows —

—	Cases examined	Positive effect.	No effect
Inacidity and subacidity	55	45	10
Superacidity	70	60	10
Ulcus ventriculi and duodeni—			
Superacid	39	34	5
Normacid	2	0	2
Inacid	[illegible]	2	0
Heterochylia	7	7	0
Cholecystitis chronica	11	6	5
Colitis chronica	5	0	5
—	191	154 (80 %)	37 (20 %)

For comparison we append those reported by László[4] also using optacid from the II University Medical Clinic in Budapest —

—	Cases examined.	Positive effect.	No effect.
Inacidity and subacidity	40	30	10
Superacidity	14	8	6
Ulcus (superacid)	13	10	3
Chronic cholecystitis	1	0	1
Heterochylia	6	4	[illegible]
—	94	72 (77 %)	22 (23 %)

We conclude that, taking the two hospitals together this remedy has benefited about 80 per cent of the patients to whom it has been given and we hope it will have wider trial.

We are Sir yours faithfully

S GERÖ M D

Budapest. F KŐRÖSY Ph D

LEEDS GENERAL INFIRMARY —This hospital as announced *in our last issue (p 97), has collected the* £250 000 which it requires to carry out its plan of improvements and extensions A pay block and new blocks for housing the nurses are needed; 140 additional beds are also to be provided for the nursing staff and a sick bay and recreation room

FALSE CALLS FOR AMBULANCES —Since Jan 1st any person who gives false information which would reasonably lead to the dispatch of one of the London County Council's ambulances is liable to a penalty up to £25 unless he can show that he had cause to believe that his information was correct This provision has been obtained by the London County Council in its General Powers Act of 1935 in view of the large and growing number of false calls which may have been malicious in origin, received in the last few years by the London Ambulance Service

PUBLIC HEALTH

VACCINATION IN THE CONTROL OF SMALL-POX

By Duncan Forbes, M.D., D.P.H.
MEDICAL OFFICER OF HEALTH FOR BRIGHTON

There are two types of small-pox: a severe form (variola major) with a mortality of 1 in 5 in unvaccinated persons, and a mild form (variola minor) which is not a killing disease even in the unvaccinated. Both forms breed true. As no Government would dream of enforcing general infant vaccination to control the mild form of the disease, I need only consider the effect of the present Vaccination Acts and regulations upon variola major.

Of first importance is an appreciation of the effect of successful vaccination. If an unvaccinated person, within 48 hours of contact with a case of small-pox, is vaccinated with potent lymph he will not develop small-pox. It is because of this that when a case of small-pox occurs the medical officer of health proceeds to staff his small-pox hospital with nurses, maids and porters irrespective of whether or not they have been vaccinated. What he never fails to do is to vaccinate the whole staff as soon as possible, and always before 48 hours have elapsed from their first contact with the case of small-pox. It is only because the medical officer can put this cordon of recently vaccinated and therefore immune persons around the small-pox patient that successful isolation is made possible.

Whilst there is then no doubt that a small-pox attack is prevented by recent successful vaccination, the number of years the vaccinated person remains immune is variously stated. The length of this period varies with the individual but depends more or less on the method of vaccination. For instance, a vaccination of four marks resulting in half a square inch of scar, as required of public vaccinators in times gone by, will protect with reasonable certainty for some 10 years and usually longer, whilst a one-mark vaccination with a tiny scar, as allowed by the Vaccination Order of 1929, probably protects for a shorter period. The evidence is more definite regarding the effect of vaccination on the severity of attack after immunity has gone. Tables in the annual report of the medical officer of health of Manchester for 1904 show that the severity of attack varies inversely as the number of vaccination marks and their total scar area. They also demonstrate how little protection is afforded by a one mark as compared with a four-mark vaccination, the deaths being in the proportion of four-mark 1, one-mark 5, unvaccinated 9. The figures for scar areas are even more striking—viz., over half a sq. in. 1, under half a sq. in. 10, unvaccinated 19.

Cases of small-pox vary much in their degree of infectivity, but are most infectious in the first few days of the rash. This may be due to the varying extent of the rash on the mucous membranes of the mouth and throat and the incidence of cough leading to rupture of the vesicles and infection by spray. The early infectivity of small-pox is important, as the first cases in a locality may not be diagnosed until the third or fourth day of the rash or later when the vaccination of contacts may fail to prevent secondary cases.

PRESENT METHOD OF CONTROL

When a case of small-pox (variola major) occurs a medical practitioner is almost invariably called in and he either notifies the case as small-pox or calls the attention of the medical officer of health to his suspicion. If the case turns out to be small-pox, within an hour or two of diagnosis, in urban areas where lymph is easily procurable, the home contacts have been vaccinated. Contacts further afield are offered vaccination as soon as possible. The offer of vaccination at the time that contacts are first told of the risk of infection is important, as when offered at once there is a higher acceptance rate; further it leads to a greater proportion of contacts being vaccinated within 48 hours of infection and any attack prevented with certainty. The next step is for the medical officer of health to let all general practitioners in the district know that a case (or cases) of small-pox has occurred and to express his willingness and even anxiety to see any doubtful rashes. This ensures that no cases are overlooked if a doctor is called in.

After the diagnosis of the case and its isolation the most important of all measures for the prevention of spread is the ascertainment of every person who has been in contact with the patient between onset and removal. By careful and repeated inquiries from the patient and his relatives a list of contacts is made out and these are visited daily about the time they are likely to develop the disease. In this way their isolation, should they develop the disease, is ensured practically from the onset. If the supervision of contacts can be, and is, efficiently carried out the small-pox outbreak is quickly brought under control. There are in fact only three ways in which it may escape immediate suppression.

(1) When the attack is so mild that a practitioner is not called in. This happens most frequently in the mild type of small-pox and makes such outbreaks much more difficult to control, especially as there is at times intentional concealment to escape removal to hospital and to prevent loss of time at work. Although mild cases of variola major also occur due usually to the effect of earlier vaccination and at times to natural resistance to attack, in all but exceptional cases a doctor is called in.

(2) When a practitioner is called in but fails to diagnose the disease and does not think it suspicious enough to report to the medical officer of health; this is the more likely to occur nowadays as many young practitioners have never seen a case of the disease. Under such circumstances a crop of cases may occur before the medical officer hears of the first case, but even then once the presence of small-pox is discovered its spread is quickly controlled.

(3) If the primary case is a tramp or person with no fixed abode, associating with like persons, the contacts cannot be efficiently supervised. Even if a tramp is known to have been in contact with a case of small-pox he cannot be compelled to accept vaccination, to have his movements controlled, or to state his place of destination. Thus the disease may spread via common lodging-houses and casual wards to the general public and be difficult to control.

HISTORY OF INFANT VACCINATION

Although vaccination was made compulsory in 1853 it was not until after the passing of the Acts of 1867 and 1871 that a high percentage of infant vaccination was obtained. Thereafter, for a time, as many as 95 per cent. of infants were vaccinated, but even so it took many years before any large percentage of the population had been vaccinated. In those times when epidemics were frequent compulsory vaccination was fully justified and was followed by a fall in the incidence of the disease amongst children and adolescents and later by a fall in case-mortality Considering the less efficient training and small number of health staffs at that time the continued occurrence of epidemics is not a matter for surprise If however it had then been realised that vaccination protects from attack for a limited period only and if revaccination at school leaving age and again in later life had also been made compulsory small pox could have been controlled by vaccination alone The compulsory system might indeed have been extended had it not been for the success attending the discovery immediate vaccination and supervision of all contacts The work of medical officers of health showed that by these means they could easily have stopped outbreaks in their areas if they had been given power to control the movements of tramps *and other migratory persons who were known to* have been in contact with small pox.

Under the circumstances related, a business man would have openly dropped *compulsory* vaccination altogether he would have given the medical officer of health power to control the movements of migratory contacts and would have relied upon intensive action by the health staff to prevent spread of the disease Instead of this compulsory vaccination was really dropped in 1907 but it was stilled called compulsory and the old cumbersome and expensive methods were retained Thus whilst the provisions of the Act of 1898 required that objectors had to *satisfy* two justices or a stipendiary magistrate that he conscientiously believed that vaccination would be prejudicial to his child's health, the Act of 1907 *only required the parent to make a statutory declaration* of conscientious objection before a magistrate Since 1907 vaccinations as a percentage of births have fallen from 71 to 30 and are still falling Not only so but in 1929 the central authority taking unnecessary fright at the possibility of post-vaccinal encephalitis occurring in infants under 6 months of age recommended a one-mark vaccination by the public vaccinator in place of a four mark vaccination In these ways the Vaccination Acts have been rendered useless first by the reduction of the percentage vaccinated but mainly by the introduction of inefficient vaccination

FUTILITY OF THE PRESENT SYSTEM

For years the futility of the present procedure has been recognised and in 1932 the Law Committee of the *Association of Municipal Corporations* considered a letter from the Ministry of Health asking them for any proposals they desired to make in the light of two years experience of the new regulations for facilitating the general acceptance of vaccination and preventing the spread of small pox They conferred with the Society of Medical Officers of Health and agreed with the recommendation of the latter body that *compulsory* vaccination should be abolished but that facilities should still be provided for vaccination and revaccination against small pox on a voluntary *basis*

In 1934 the British Medical Association set up a committee to consider how best to inform the public of the protection afforded by various methods of immunisation including vaccination Their report supported general vaccination and revaccination as important in the prevention of epidemics of small pox but added[1]:

> "It seems likely that the retention on the Statute Book [of the Vaccination Acts at present in force] will soon serve no practicable purpose In so far as they foster antagonism to vaccination they hinder the acceptance of other forms of immunisation

Although all these expressions of opinion must be well known to the Ministry of Health it must be difficult for them to take action unless such action is demanded by public opinion To help to create this it would be well that the public and particularly parents and magistrates should be informed of the following facts

The public health service is well able to control outbreaks of virulent small pox apart altogether from *routine vaccination of infants provided that full* powers are given to them to supervise migratory small pox contacts

The chance of anyone being infected with virulent small pox in this country is very remote (1 in 50 000 in my area in the last 25 years) At the same time the parents should bear in mind that if the unvaccinated are infected by virulent small pox 1 in 5 dies that the face is greatly disfigured by pock marks and that efficient vaccination is in the nature of an *insurance against such a risk*

As the present one mark vaccination is of relatively small value parents must ask for two to four marks with a resulting half sq in scar area

The cost of the present system should be estimated and compared with that of a voluntary system from which all unnecessary records are dropped and vaccination carried out at a municipal centre where similar work for immunisation against diphtheria is undertaken The wastefulness of the present system compared with its small value in both time and *money could thus be made apparent and with* public opinion in favour of new legislation I have little doubt that at no distant date the present Acts would be repealed a purely voluntary system introduced and greater powers given to medical officers of health to keep migratory contacts under supervision.

INFLUENZA

THE number of deaths from influenza reported from the Great Towns in the week ending Jan 9th 1937 was 768—a figure for which the recent trend of the outbreak had prepared us

We reproduce this week a graph showing the deaths from influenza during the winters of 1932–33 and 1935–36 with the corresponding graph for 1936–37 so far as the figures are at present available (The data from which the graph is drawn are *given at the foot*) As the weeks do not strictly correspond in the three years we have plotted the deaths against the last day of the week to which they relate in each year It should be borne *in mind* that the graph relates only to deaths and not to attacks and there is evidence from all parts of the country that the disease is still taking a mild form with the normal age-distribution and no emphasis on young adults as in the pandemic of 1918 The line for 1937 runs so far closely parallel to that for 1933

Of the 768 deaths from influenza reported in the week ended Jan 9th 1937 558 were in the south eastern area (including London) 98 in the Midlands 87 in the north, 18 in Wales 5 in the south west and 2 in the eastern counties

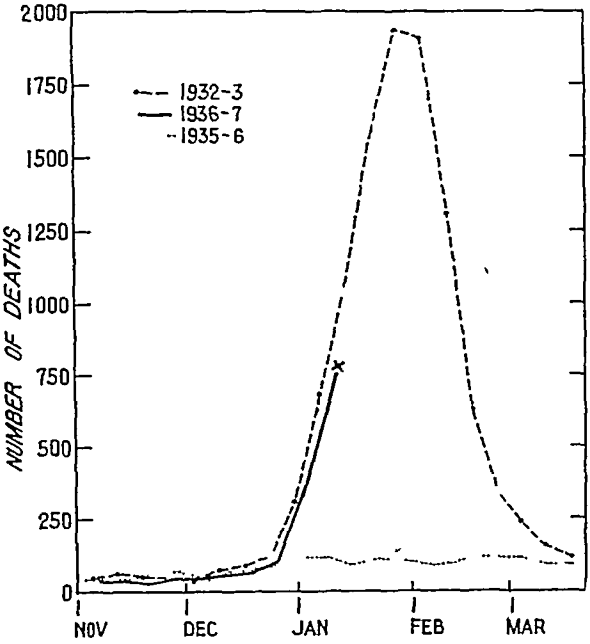
Of the [illegible] deaths from influenza reported in the week ended Jan. 2nd 1937 128 occurred in London and 232 in Greater London The numbers in the Outer Ring were in diminishing order: Willesden 12; Ealing 9

---

[1] *Brit. med. J.* 1935 1 192 (Supp.)

Hendon, 7, West Ham, 6 Walthamstow, 5, Acton and Hornsey, each 4, Brentford, 3, East Ham, Harrow, Leyton, Southgate, and Wembley, each 2, Barking, Beckenham, Enfield, Mitcham, Wimbledon, and Wood Green, each 1 Outside London the number of deaths in diminishing order was as follows Bristol, 17, Bradford, 10, Leeds, 9, Birmingham, 8, Northampton, 7, Nottingham, 6, Leicester, 5, Manchester, Cardiff, and Rhondda, each 4, Reading, Southend on Sea, and Liverpool, each 3, Brighton, Canterbury, Hove, Sunderland, Derby, Ipswich, and Swansea, each 2

It is perhaps worth pointing out that the abruptness of the increase in the week ending Jan 2nd was attributable in part to imperfect returns in the previous week, which included two holidays A study of the comparative table of total annual death rates in various great towns confirms this surmise From this it appears that the death rate in the 122 great towns taken together increased from 10 8 to 17·0 but as the figures for the two previous December weeks were 12 4 (Dec 12th) and 13 3 (Dec 19th) it seems not unlikely that the actual rise in the death rate between Dec 26th and Jan. 2nd is nearer 2 than 5 Applying the same adjustment to the other figures in the same table, it is clear that while there has been a sharp rise in London and Bristol, and a less but still material rise in Bradford, Liverpool, and Nottingham, the increase in the death-rate at such places as Birmingham, Manchester, and Newcastle-on Tyne may be more apparent than real.



Graph showing total deaths from influenza in the Great Towns on the last day of each week in three different years.

THE SITUATION IN LONDON

The number of beds allocated to influenza in the L C C fever hospitals is now 700 On Saturday, Jan 9th, there were over 1600 cases in the general hospitals and 513 in the fevers This is an increase over the previous week, but from the returns of admissions it does not appear that the demand for hospitalisation is increasing The number of patients remaining under treatment will of course continue to increase until the discharges are greater than the admissions The Registrar-General's figures for the week ending Jan 9th show 311 deaths certified as due to influenza in London compared to 128 in the preceding week Notifications of acute primary or influenzal pneumonia were 408 in the week ending the 9th, compared with 290 in the previous week. The clinical picture remains much the same, there is no evidence that pneumonia is occurring with more than average frequency or manifesting the dreaded toxic attributes of the 1918 pandemic A considerable degree of prostration and depression seems to persist for some days after the temperature has fallen to normal. Many of the L C C nursing staff are still incapacitated

NEWS FROM THE COUNTRY

The information given last week has been substantially confirmed since, except that Nottingham and its neighbour Loughborough seem now to have suffered as severely as any places outside London. In Birmingham the disease though widespread has remained mild Bradford is reported to have suffered most among the Yorkshire towns, transport drivers and other officials having been down in large numbers but as elsewhere attacks were of minor severity and short duration In Leeds also the public utility services have been much inconvenienced Around Newcastle-on Tyne there has been a slight increase in febrile illnesses but nothing which can be called an epidemic, while the outbreak of nausea and vomiting has definitely subsided, deaths from pneumonia are not above the average for the time of year At Brighton the epidemic is still active but not increasing, as time goes on there are more relapses, the depression however if severe does not last long Here as elsewhere the few cases of sequential pneumonia have not been severe or toxic

---

ACUTE POLIOMYELITIS

THE Ministry of Health has issued a revised memorandum (166/Med 2*d*), the text of which follows closely that of the original, published in 1932, but differs in important particulars which reflect the growth of our knowledge of poliomyelitis during the past four years Since the first memorandum was published America and Australia have added most to our knowledge of the epidemiology of poliomyelitis and England the least, for the satisfying reason that the disease is less frequent in Britain than in any other part of the civilised world The memorandum states "There is no sufficient reason to believe that the virus of poliomyelitis is conveyed to man by foodstuffs or insects, or that the disease is associated with insanitary conditions" These words are identical in both issues, but whereas in 1932 there was proof that the virus is conveyed in these ways in 1936 there is strong evidence that it is not Differences in the paragraphs on epidemiology and pathology are due to the Ministry accepting the conclusion of the neurologists that poliomyelitis is primarily an infection of the neurons directly through the filaments of the olfactory nerves Formerly it was believed that the course of the disease was nasal catarrh septicæmia invasion of meninges and lastly implication of the neurons—and that the disease could stop at any of these stages In other words that poliomyelitis is an acute fever which may or may not have infantile paralysis as a complication. The new view is that poliomyelitis is a direct infection *of the neurons which may or may not lead to* permanent paralysis, but there is no disease without implication of the neurons It is well to keep open the question whether man may react otherwise than by poliomyelitis to the virus, but it may be accepted that unless the neurons are implicated at the start they never will be The memorandum mentions that the cephalic form (polio-encephalitis) usually ends in death or complete recovery though it does not always do so The paragraph on treatment in the new memorandum differs from that in the old more in tone than in words owing to the fact that in 1932 convalescent serum gave great promise whereas, unfortunately in 1936 hope of serum treatment had fallen almost to zero 'The after-effects of poliomyelitis are of so grave a nature that in spite of these findings some medical practitioners may still desire to use serum This is not encouraging but it may be the best that can be said with truth. There is no material alteration in the paragraphs on precautions against infection and on the action by the medical officer of health It is doubtful whether any of the precautions is of much avail. Since in epidemic centres passive carriers are vastly more numerous than cases or known contacts isolation does not *promise much* but the evidence from Queensland that contacts are mainly responsible for the spread of the disease is not to be ignored. It has been questioned whether actual sufferers can spread the disease after symptoms have developed The late James Collier held that they could not We are told

Neither serum nor specific vaccines can be recommended for individual protection While we do not cavil at this statement in 1936 we may well hope that the future will give us a vaccine which is both trustworthy and free from danger

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JAN 2ND 1937

Notifications—The following cases of infectious disease were notified during the week: Small pox 0; scarlet fever 1933; diphtheria, 1353; enteric fever 18; pneumonia (primary or influenzal) 1612 puerperal fever 40 puerperal pyrexia 150 cerebrospinal fever 33; acute poliomyelitis, 2; encephalitis lethargica, 3; continued fever 1 (Brighton); dysentery 10; ophthalmia neonatorum, 71 No case of cholera plague or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Jan 8th 1937 was 2805 which included: Scarlet fever 953 diphtheria 1011 measles 15; whooping cough, 496 puerperal fever 14 mothers (plus 8 babies) encephalitis lethargica 285; poliomyelitis, 4 At St Margaret's Hospital there were 13 babies (plus 6 mothers) with ophthalmia neonatorum

Deaths—In 122 great towns including London there was no death from small pox 1 (1) from enteric fever 7 (0) from measles, 0 (0) from scarlet fever, 28 (7) from whooping-cough 41 (5) from diphtheria, 52 (17) from diarrhœa and enteritis under two years and 825 (128) from influenza. The figures in parentheses *are those for London itself*

Nottingham had 3 deaths from whooping-cough Fatal cases of diphtheria were reported from 33 great towns Liverpool and Birmingham each 4

The number of stillbirths notified during the week was 302 (corresponding to a rate of 44 per 1000 total births) including 44 in London.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg Comdr G Kirker to *Pembroke* for R N.B

Surg Lt -Comdr C Ommanney Davis retires at own request

Surg Lt (D) F J Goldsworthy promoted to rank of Surg Lt -Comdr (D)

C E Fitton H W Gibbs and R A. Hilton to be Surg Lts (D)

Surg Lt C J Mullen to *Drake* for R.N.B

Surg Lt D Ewart transferred to Emergency List

The following have received appointment as Surg Lts for Short Service: W Boyd (Glasgow Univ) F A Crosfill (Leeds Univ) G C Denny (Guy's Hosp) F P Ellis (Manchester Univ and Charing Cross Hosp) R Vaughan Jones (Birmingham Univ) W Sloan Miller (Glasgow Univ) L. R Norsworthy (St Bartholomew's Hosp) B O Neill (Cork Univ Coll) G R Rhodes (Manchester Univ) and P G Stainton (Guy's Hosp); and appointed to R N Hosp Haslar for course

G H C R Crition entered as Surg Lt for short service

ROYAL NAVAL VOLUNTEER RESERVE

Surg Lts W S Miller and R V Jones, commissions terminated on transfer to R.N

ROYAL ARMY MEDICAL CORPS

Maj -Gen H Ensor CB CMG CBE D.SO ret pay (late R.A.M C) is apptd. Col. Comdt vice Maj -Gen O L Robinson C.B C.M.G ret pay (late R.A.M.C) who has attained the age limit for his appt

Capt T F M Woods to be Maj

TERRITORIAL ARMY

Supernumerary for service with the O T C Lt.-Col. J du P Langrishe D S O (Lt -Col Res. of Off) resigns his commn. in the T.A

ROYAL AIR FORCE

Wing Comdr R H Stanbridge to Princess Mary's R.A.F Hospital, Halton for duty as medical officer

Flight Lts I A Cooper to No 31 (Army Coöperation) Squadron, Karachi India; C M Fraser and J F McGovern to Central Medical Establishment London; and W P Stamm to R.A.F Station, Abbotsinch

Dental Branch—Flight Lt J E. Tyrrell to R.A.F Station Calafrana Malta

Flight Lt P J Clifford Keane is transferred to the Reserve class D

INDIAN MEDICAL SERVICE

Majs to be Lt Cols: L. G Pearson and P M Antia.

The undermentioned appts. are made:—

To be Capt (on prob): A H O'Malley

To be Lts. (on prob): A M McGavin J D O'Shaughnessy J F O Donnell and D R. Cattanach.

The undermentioned appt has been made in India:—

D.A.D.M.S.: Bt Lt -Col. A. H Craig I.M.S

The undermentioned officers have vacated appts in India:—

D.A.D P: Lt -Col A C Craighead I.M S

D.A.D.M.S: Lt -Col. C A. Wood M.C I.M.S.

FOR AMATEUR ACTORS AND PRODUCERS—A practical course of acting play production, and stagecraft will be held at the Everyman Theatre Hampstead on Sunday afternoons, Feb 7th 21st 28th and March 14th 21st and 28th. During April and May a series of public performances will be given by members of the course Further particulars may be found in our advertisement columns.

OBITUARY

SIR DAVID SEMPLE, M D R U I

LATE DIRECTOR OF THE PASTEUR INSTITUTE INDIA

THE death occurred on Thursday, Jan. 7th, in St Mary's Hospital of Sir David Semple, who will always be remembered in association with antirabies therapeutics, and whose general contributions to tropical medicine were of the first order

David Semple was the second son of the late William Semple of Castlederg, Co Tyrone He was born in 1856 and received his early education at Foyle College, Londonderry, and Queen's College, Belfast He graduated as M.D , M Ch R U I with honours in 1881, and entered almost immediately the Royal Army Medical Corps He served with the Corps for some five years, leading an active regimental life, with polo as a particular interest But in 1893 he went to Cambridge and occupied his leave by studying bacteriology under Sims Woodhead. He then began his association with Sir Almroth Wright, under whom his later bacteriological work was done, and when Sir David Bruce left for S Africa to carry out his brilliant studies of the tsetse fly, Semple was selected by Wright as Bruce's successor to be assistant professor at Netley He proved a good teacher, while he collaborated closely with Wright in the early work on typhoid inoculation and on Malta fever, during which latter investigation both the researchers contrived to infect themselves At Netley Semple gained his early insight into Pasteur's antirabic work, for at this time Pasteur's methods were a regular subject of demonstration to the students at the Army Medical School When his appointment at Netley was up he went to Paris and studied the antirabic treatment at the Pasteur centre so that on proceeding to India in 1899 he was especially well equipped for the important opening which now came to him

SIR DAVID SEMPLE

[Photograph by Elliott & Fry

We owe to Sir Rickard Christophers the following full summary of Sir David Semple's work in India

"Though it is now more than twenty years since Sir David Semple retired from active work in India his name will be fresh in the minds of a great many who knew him personally and an even greater number who know him by reputation Few in the medical services in India have ever been so well and widely known, personally and by reputation He was the father of antirabic treatment in India and came to be regarded almost as a seer by many thousands of Indians and hundreds of Europeans who in the course of years have travelled to Kasauli to receive antirabic treatment or advice But this is not the only reason why Sir David Semple's name was well known Coming to India at a time when there was practically no organisation for medical research in that country and no such thing as courses of instruction as at present in schools of tropical medicine at home Sir David Semple as teacher and organiser for many years represented all that was most modern and progressive in scientific medicine and an inspiration not only to those of his own service in India but even more so perhaps to many young Indian Medical Service officers with whose work his own became increasingly associated He was definitely the founder of the two institutes at Kasauli, the Pasteur Institute of India and the Central Research Institute and as such played a very considerable part in the eventual development of medical research in India, since from both these institutes have come many of the future directors of the now numerous laboratories, and Pasteur institutes that have since arisen in various parts of India

"There can be little doubt that Sir David Semple's success in India was in considerable part at least due to the time he had spent before arriving in that country as assistant professor of pathology at Netley with Sir Almroth Wright, and to his work under Pasteur at Paris Trained in such an environment he came equipped not only with a sound knowledge of bacteriology and bacteriological and serological technique but also imbued with the spirit of a new revival in medical research which had begun to be evident at this time Very probably, the present writer thinks, Semple must have been sent to Paris with the definite object of enabling him to put into concrete form a scheme for a Pasteur institute in India which had already been some time under consideration, and in which Sir Almroth's advice had at some previous time been asked. Whether this be so or not, David Semple in 1899 came out to India equipped as few before him had been to take charge of activities in a virgin field On April 9th, 1900, the Pasteur Institute of India was opened with Sir David Semple (then Major Semple) as director In the first year some three hundred patients were treated. It is impossible to read the early annual reports of this new institute, the first of its kind in the British Empire, without being deeply impressed not only with the energy and initiative displayed by its founder, but also by the enlightened spirit which evidently actuated him in all the work done Looking back one sees even in the early years of the Institute's existence the original birth of activities which have since grown but which are still much as started by Semple The production and issue of antivenine—a serum prepared against cobra bite, and later including also protective properties against the dreaded Daboia or Russell's viper—had already been started even as early as 1903 A serum against rabies (as distinct from a protective vaccine), now used in certain cases, had already been prepared and tried. Antityphoid vaccine and even diphtheria and tetanus serum were likewise prepared and the use of the laboratory for diagnostic purposes to assist R.A M.C and I.M.S officers and private practitioners was already in 190 recognised An entirely new type of institute, such as is now familiar enough, had thus been created for the first time in India and probably for the first time in any tropical British Possession.

"Schemes for more effective laboratories in India had however for some time been receiving increased attention and under the régime of Lieut. Colonel Leslie, Sanitary Commissioner with the Government of India, there was brought about the formation of a bacteriological department with recognised laboratories for the Central and Provincial Governments and a fixed bacteriological cadre much as has since existed In this scheme Semple became the first director of the Central Government s laboratory the Central Research Institute at Kasauli It was again due to Semple s personal energy and capacity for organisation that this institute came into being and continued to function not only as a centre for research but one from which a spirit has been infused that has had a great directive influence on the future development of medical research in India

‘During his time as director of this new institute Sir David Semple made some important contributions to medical science Among such may be mentioned the results of an inquiry into the methods by which enteric fever was contracted in the British Army in India results which greatly modified the existing outlook on the causes of this disease among troops and the steps to be taken to prevent it Perhaps the research of greatest practical importance was that which dealt with the protective properties of carbolised dead vaccine in rabies He showed that such vaccine could be used with effect in place of the living virus which was the basis both for the dried cord method and the dilution method then in use Adoption of this form of the antirabic treatment has completely modified previous ideas as to the necessity of the patient travelling long distances to be treated in a hill station, and has allowed of the present method of distribution of the vaccine to numerous inoculation centres in the plains

It is not however as the pure research worker that Semple was chiefly known but rather in the rôle of inspired organiser and teacher As the former he built well and laid an enduring basis on which others have since extended the work As a teacher his power lay in a great faculty amounting to genius for simple demonstration He had the one prime necessity for the good teacher that he never forgot that those being taught did not start with all the knowledge he himself possessed To those who knew him in private life and to those about him in the laboratory he was a staunch and kindly friend and his memory will long remain in Kasauli where he spent so many years of his life

Sir David Semple was knighted in 1911 and retired from service in India in 1913 being appointed director general of the Public Health Department in Egypt He served in Egypt throughout the war with the rank of Colonel A.M S and received the Order of the Nile He married Ethel May daughter of Dr Edward Watson of Isleham Cambs and was the father of seven children of whom three daughters survive Of four sons two were killed in the war and two died in youth

THE LATE SIR GRAFTON ELLIOT SMITH

Dr A J E Cave assistant conservator of the museum of the Royal College of Surgeons of England writes The outstanding achievements of the late Sir Grafton Elliot Smith in the field of cultural anthropology may be less familiar to his medical brethren than are his pioneer investigations into mammalian cerebral anatomy or his important contributions to the physical anthropology of primitive and of fossil man Yet his influence in this particular field (one of increasing social and politico economic importance) has been as profound as that of a Darwin or a Huxley in realms biological indeed no more may the modern ethnologist neglect a thoughtful recognition of Elliot Smith s doctrine of the diffusion of culture than the present-day biologist may dispense with some scheme at least of organic evolution

The potent influence which Elliot Smith was later to exert had its seeds in his chance occupancy of the Cairo chair of anatomy which brought him into close and sympathetic coöperation with the foremost Egyptian archæologists of his day (Maspero Junker Reisner Mace Quibell Theodore M Davis and others) and gave him an unrivalled acquaintance with Egyptian cultural elements of all periods of that country's history His anatomical skill was sought increasingly in the description and recording of extensive series of human remains (cf. his contributions to the *Bulletins* of the Archæological Survey of Nubia) and in the examination of many historic and other mummies the volume on The Royal Mummies of the Cairo Museum Catalogue being from his pen. His numerous memoirs on mummification (continued in after years) not only gave us the first truly scientific and comprehensive analysis of this curiously distinctive practice but also focused their author s attention sharply upon a ritual which he recognised as constituting the central nucleus of the whole of ancient Egyptian civilisation Elliot Smith intuitively perceived in the practice of mummification one of the master themes of cultural anthropology a theme which he expanded and elaborated in later years to most fruitful purpose It was originally from the mere geographical distribution past and present, of this peculiar and difficult practice that he demonstrated (1915) The Migrations of Early Culture a classic of ethnological accomplishment

He sought increasingly with his colleague Dr W J Perry and the disciples they gathered about them corroborative evidence of the actual spread of cultural elements and customs from one original home and whilst such evidence accumulated he proclaimed, with characteristic fullness and vigour his provocative ethnological doctrine of the diffusion of culture Tremendous even bitter was the opposition to this novel teaching and the echoes of conflict are still about our ears. But in the main the old fallacy of a basic psychic unity underlying human activities and reactions was exploded and the gist of later anthropological investigation has been a confirmation of the truth and reality of the main tenets at least of the diffusionist gospel and of Elliot Smith s penetrating conception regarding the fundamental uniformity of early civilisations The whole face of ethnological study has been renewed and a new and vivifying spirit infused therein.

It is to Elliot Smith s lasting credit that he first with an intuition transcending the merely anatomical, perceived in Ancient Egypt the essential threads of primitive culture and civilisation and out of them wove on the loom of his genius the tapestry of human history

---

Congress of Fever Therapy—As announced in our issue of Dec 26th, the first International Congress of Pyretotherapy will be held at Columbia University New York on March 29th 30th, and 31st We are informed that Dr Germain Blechmann 30 avenue de Messine Paris VIII is drawing up a report on pyretotherapy in pædiatrics and asks that all interested should send him their publications on the subject and a résumé of communications they would like to put before the congress. The British secretary for the congress is Dr W Kerr Russell 146 Harley-street London W 1 and the secretary-general Dr William Bierman 471 Park avenue New York.

MEDICAL NEWS

University of London

On Tuesday, Jan 19th, Prof J C Drummond will give the first of six weekly lectures on problems of nutrition, and on Monday, Jan 25th, Mr H R Ing, D Phil., will give the first of six lectures on *chemical structure and pharmacological action* These lectures will all be held at 5 P M at University College, Gower street, W C Five Heath Clark lectures *on the development of bacteriology with some account of the pioneers who have made it a science* will be given at the London School of Hygiene, Keppel street, W C, on Jan 25th, 28th, and Feb 1st, 4th, and 8th, at 8 P M, by Dr William Bulloch, F R S, emeritus professor of bacteriology in the University On Tuesdays, Feb 9th, 16th, and 23rd, at St Mary's Hospital medical school, at 5 30 P M., Mr E D Telford, emeritus professor of systematic surgery in the University of Manchester, will lecture on some disorders of the peripheral circulation They are open to all interested in the subjects

The following have been recognised as university teachers at the schools indicated Mr J P Hosford, Dr James Maxwell, and Dr A W Spence (St Bart 's), Dr J D Benjafield, Mr Ralph Marnham, and Mr T F McNair Scott (St George's), Mrs Joan Taylor (Royal Free), Mr B W Fickling and Mr D G Walker (London School of Dental Surgery), Mr Percival Hartley, D Sc, and Sir Patrick Laidlaw (National Institute for Medical Research)

At recent examinations the following candidates were successful —

M D

Branch I (Medicine) —J A Brocklebank, Guy s Hosp A M R Cann Middlesex Hosp E A Danino, St Bart. s Hosp C J Gavey London Hosp N M Green, Univ Coll Hosp R R Henderson, A L P Jeffery and Evan Jones St Thomas s Hosp E I Jones, King s Coll Hosp, F A Jones, St Bart. s Hosp A L Light Univ of Leeds G A. M Lintott, Guy s Hosp Mary F Lockett, Roy Free Hosp Brian McArdle Guy s Hosp, D C Reavell St. Bart 's Hosp, A. M Stewart Wallace Univ Coll Hosp, and J B L Tombleson, St. Thomas s Hosp

Branch II (Pathology) —G J Cunningham and A H T Robb Smith (university medal) St. Bart s Hosp

Branch III (Psychological Medicine) —A. C Dalzell (university medal) King s Coll Hosp

Branch IV (Midwifery and Diseases of Women) —Agnes V Kelynack, Roy Free Hosp L W Lauste St Thomas s Hosp G G Macdonald Univ Coll Hosp Marjorie E Roberts Roy Free Hosp, J W Schabort Guy s Hosp and Postgraduate Medical School, and Violet H Whapham, Roy Free Hosp

Branch V (Hygiene) —Karl Biden Steele, Guy s Hosp

Royal Faculty of Physicians and Surgeons of Glasgow

At a meeting of the faculty held on Jan 4th, with Prof Archibald Young, the president in the chair, the following were admitted to the fellowship —

Jacques Simon Cramer (Fiji) Rustom Ardeshir Davar (London) Alexander Hutchison and Agnes Thomson Kennie (Glasgow), Sydney Mander Laird (Kilmacolm) Patrick Joseph Molloy (Glasgow), Benoy Bhusan Mukerjee and Charu Chandra Saha (London) and Tanjore Somosundara Subramaniam (Liverpool)

International Surgical Congress

The next congress of the International Surgical Society is to be held in Vienna in 1938, and arrangements are now being made The subjects of discussion will be the surgical treatment of arterial hypertension bone grafts and the surgical treatment of cysts and pulmonary tumours Members of the society who would like to take part are asked to communicate with Prof Grey Turner at the British Postgraduate Medical School, Ducane road, London, W 12

Conference on the Accredited Milk Scheme

On Jan 28th as already announced the Royal Sanitary Institute is holding a discussion on the administration of the Milk (Special Designations) Order, 1936 with respect to accredited milk A large attendance is expected and it has therefore been decided to transfer the meeting from the house of the institute to the Central Hall, Westminster It begins at 2 P M Mr Thomas Baxter, chairman of the Milk Marketing Board will preside, and Dr W G Savage, medical officer of health for Somerset, will open the discussion

THE American Congress of Physical Therapy has awarded to Dr Stefan Jellinek, professor of electropathology in the University of Vienna, its gold key for distinguished service, and has elected him an honorary life member A note describing Prof Jellinek's museum of electropathology was published in our issue of Nov 14th, 1936, p 1195

Research in Encephalitis

The foundation of the advancement of encephalitis research, at the University of Berne, offers prizes to workers in that field Particulars will be found in our advertisement columns.

Hunterian Society

The Hunterian lecture of this society will be delivered at the Mansion House, London, at 9 P M on Monday Jan 18th, by Dr J Schoemaker of The Hague He will speak on the surgery of gastro-duodenal inflammation.

Royal Microscopical Society

The annual meeting of this society will be held at B M.A House, Tavistock square, London, W C, on Wednesday, Jan. 20th, at 5 30 P M, when Mr R S Clay, D Sc, will deliver a presidential address on the mechanical development of the microscope

A Hospitals Emblem

Hospitals Week in London and Greater London is timed for May 2nd–8th, immediately before the Coronation Over 80 hospitals are uniting in a combined attempt to raise funds, and this will take the place of the flag days previously scattered throughout the year The committee organising Hospitals Week, whose chairman is Lord Luke, is in search of an emblem that can be made as familiar to the public as the red cross and the Flanders poppy Suggestions may be addressed to the hon. secretary, Hospitals Week, 36, Kingsway, London, W C 2 but no prizes are offered

B M A Scholarships and Grants in Aid of Research

The Council of the British Medical Association is prepared to receive applications for research scholarships and grants for assistance of research in connexion with disease

Scholarships —An Ernest Hart memorial scholarship, of the value of £200 per annum a Walter Dixon scholarship value £200 per annum and three research scholarships each of the value of £150 per annum These scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject relating to the causation prevention or treatment of disease Preference will be given other things being equal to members of the medical profession Each scholarship is tenable for one year commencing on Oct 1st 1937 A scholar may be reappointed for not more than two additional terms and is not necessarily required to devote whole time to the work of research but may hold a junior appointment at a university, medical school or hospital provided the duties of such appointment do not interfere with the work as a scholar

Grants —Grants for the assistance of research into the causation treatment or prevention of disease will be made Preference will be given other things being equal to members of the medical profession and to applicants who propose as subjects of investigation problems directly related to practical medicine

Applications for scholarships and grants must be made not later than Saturday May 8th 1937, on the prescribed form, a copy of which will be supplied on application to the medical secretary of the Association, B.M A House, Tavistock square, London W C 1 Applicants are required to furnish the names of three referees who are competent to speak as to their capacity for the research contemplated

The Council will also consider the award of the Katherine Bishop Harman prize for the year 1938 The purpose of the prize the value of which is £75, is the encouragement of study and research in connexion with risks of pregnancy and childbearing, and the competitor, who may be any registered medical practitioner, is left free to select the work to be presented, provided it comes within the indicated terms The essay must be typewritten or printed in the English language, distinguished by a motto and accompanied by a sealed envelope bearing the same motto and enclosing the candidate s name and address

Selly Oak Hospital

Birmingham city council have approved large extensions to this hospital which will cost over £250 000

A Woman Police Surgeon

It is announced that Dr Eleanor Margaret Reece has been appointed a divisional police surgeon to the Metropolitan Police Force This is the first appointment of a woman doctor to a post of this kind by Scotland Yard.

Society for Relief of Widows and Orphans of Medical Men

At a quarterly court of directors held on Jan 6th, with the president Mr V Warren Low in the chair six new members were elected, and one death and one resignation reported A sum of £1640 was voted from the ordinary funds, and one of £541 from the Brickwell fund for the payment of the half yearly grants to the 50 widows and 9 orphans in receipt of relief It was reported that £640 had been distributed in Christmas presents, each widow receiving £10 and each orphan £5 this in addition to their ordinary grants Particulars and application forms for membership from the secretary of the society at 11 Chandos-street London W 1

Fellowship of Medicine and Post Graduate Medical Association

From Jan 25th to 30th there will be an all-day course in chest diseases at the Brompton Hospital An intensive course in gynæcology will be given at the Chelsea Hospital for Women (Feb 8th to 20th) and a course in medicine surgery and gynæcology at the Royal Waterloo Hospital (Feb 22nd to March 6th) A week-end course will be held at the Princess Elizabeth of York Hospital for Children on Feb 20th and 21st M.R.C.P courses will be given as follows: clinical and pathological course at 8 P.M. on Tuesdays and Thursdays at the National Temperance Hospital (Feb 16th to 25th) chest diseases at 5 P.M. two evenings weekly at the Brompton Hospital (Feb 22nd to March 20th) heart and lung diseases at 8 P.M. on Mondays, Wednesdays and Fridays at the Royal Chest Hospital (March 1st to 20th); and afternoon neurology course at the West End Hospital for Nervous Diseases (March 8th to 20th) A course in anatomy and physiology in preparation for the primary F R C.S. examination will be given at 5 15 P.M. on Mondays Wednesdays, and Fridays from Feb 22nd to May 24th at the Infants Hospital Vincent square Surgical tutorial classes for F.R C.S (final) candidates are being given at the National Temperance Hospital at 8 30 P.M. on Tuesdays and Thursdays Further information may be had from the secretary of the fellowship 1 Wimpole-street W 1

Memorial to Dr R J Gittins

An extension to the pathological department of the Birmingham Children's Hospital was opened on Jan 6th by the deputy mayor of Birmingham Mr Alderman S J Grey The additional storey which has cost £3500 brings the pathological and biochemical departments under one roof and provides a biochemical laboratory 34 ft by 15 ft a museum and library 21 ft by 15 ft., and separate rooms for balances washing up of bottles and equipment There is an office and workroom for the pathologist, and an office and workroom for the head biochemist with cloak room accommodation for the department The ground floor has been reorganised and contains a large pathological laboratory with two separate workrooms for research scholars, a post mortem room refrigerator room for bodies a mortuary chapel and a record room The old biochemical department adjacent will serve for making routine media, sterilisation, &c a second room for X ray equipment for animals sections and bodies and a third as a photographic department with dark room for Price-Jones apparatus

The extension has been erected to the memory of the late pathologist to the hospital and a memorial tablet was unveiled bearing the following inscription:—

> "This tablet records the extension of the Pathological Department in memory of Robert John Gittins M.D. M.R.C.P. D.T.M. & H. who rendered devoted service to the Hospital as Pathologist from 1930 1934 and gave his life in an unavailing attempt to save his son from drowning on 7th October 1934"

Maternity and Child Welfare Conference

The seventh English-speaking Conference on Maternity and Child Welfare will be held at B.M.A House Tavistock-square London, W C on June 1st 2nd and 3rd under the presidency of Sir Kingsley Wood, Minister of Health. The idea running through the whole conference is to be the further evolution of the maternity and child welfare movement throughout the British Empire and the United States of America Further information may be had from the secretary of the National Association for the Prevention of Infant Mortality (Carnegie House 117 Piccadilly London W 1) which is arranging the conference on behalf of the National Council for Maternity and Child Welfare

British Empire Cancer Campaign

Sir Cuthbert Wallace P R C.S presided at the sixty first quarterly meeting of the grand council of the British Empire Cancer Campaign held in London last Monday The council tendered its sympathy to Lady Bland Sutton in her recent bereavement the late Sir John Bland Sutton was one of the founders of the campaign and was vice-chairman of the grand council for ten years Mr Stanford Cade F.R C S of the Westminster Hospital was invited to become a member of the grand council and Sir Harold Mackintosh and Mr B T Clegg were invited to represent the Yorkshire council in addition to Lord Harewood.

The following grants in addition to those totalling £28 995 which were made at the annual general meeting in November were approved on the recommendation of the scientific advisory committee: £[illegible]00 to cover the cost of special physical investigations being carried out under the direction of Dr F G Spear at the Strangeways Research Laboratory Cambridge £500 for one year to Dr H J Phelps whilst carrying out experiments in connexion with Dr Lumsden's anti-cancer serum under the supervision of Dr Gye and Prof McIntosh, and £440 for one year to Miss C F Fischmann working in the Bernhard Baron institute of pathology at the London Hospital

---

Appointments

CRAIG J W M.D Dub has been appointed Assistant Medical Officer at Clare Hall Sanatorium (under the Middlesex County Council)

HIGGS S L, B Chir Camb, F R C S Eng., Orthopædic Surgeon to St. Bartholomew's Hospital.

JOSEPHS, H., M R C S Eng Senior Assistant Medical Officer at the National Sanatorium Benenden

MEYER, A., M B Cape Town, D M R E whole-time Officer in the X Ray *Diagnostic Department of St. Bartholomew's* Hospital

WEATHERHEAD, P L M B Lond., Resident Medical Officer at Barking Hospital

FRIDAY, Jan 22nd (London School of Hygiene Keppel street W C) —4 45 P M., business meeting 6 P M Prof. Millais Culpin The Application of Medical Psychology in Industry Followed by Miss May Smith, D Sc

SATURDAY —10 A.M (South Metropolitan Gas Co 589 Old Kent road S E), Dr W D Jenkins Clinic and Works Visit

EUGENICS SOCIETY

TUESDAY Jan 19th —5 15 P M (rooms of the Linnean Society Burlington House Piccadilly W) Dr David Forsyth Heredity versus Environment—a False Issue

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln s Inn fields W C

MONDAY Jan 18th —5 P M Mr Evelyn Sprawson Odontomes

WEDNESDAY —5 P M , Dr Russell Reynolds Movements of the Œsophagus, Stomach Duodenum, and Ileum during the Passage of an Opaque Meal

FRIDAY —Mr A S Kerr The Higher Autonomic Control of the Hollow Viscera (Hunterian lectures)

UNIVERSITY OF LONDON

TUESDAY, Jan 19th —5 P.M (University College Gower street W C), Prof. J C Drummond Problems of Nutrition (First of six lectures)

BRITISH POSTGRADUATE MEDICAL SCHOOL Ducane road W

MONDAY Jan 18th —2 30 P M Dr H MacLean Nephritis and Allied Conditions

TUESDAY —2 P.M , pathological demonstration , 3 P M Prof Schoemaker (The Hague) Acute Symptoms in the Upper Abdomen

WEDNESDAY —Noon clinical and pathological conference (medical) 2 30 P M clinical and pathological conference (surgical) 4 30 P.M Mr A. S Parkes, F R S Experimental Endocrinology

THURSDAY —Noon, clinical and pathological conference (obstetrics and gynæcology) 2 30 P.M , Dr Duncan White Radiological Demonstration 3 30 P.M Prof V H Mottram The Mother s Diet and its Influence on the Fœtus and the Newly Born Child

FRIDAY —2 P.M. operative obstetrics 2 30 P.M , Mr W B Gabriel Surgical Diseases of the Rectum 3 P M department of gynæcology pathological demonstration

Daily, 10 A.M to 4 P M medical clinics surgical clinics or operations obstetrical and gynæcological clinics or operations

WEST LONDON HOSPITAL POST GRADUATE COLLEGE Hammersmith W

MONDAY Jan 18th —10 A.M skin clinic 11 A M surgical wards 2 P M operations surgical and gynæcological wards medical surgical and gynæcological clinics 4 15 P M Mr Arnold Walker Genital Prolapse

TUESDAY —10 A M medical wards 11 A.M surgical wards 2 P M operations medical surgical and throat clinics 4 15 P M Mr Woodd Walker Pain in the Foot

WEDNESDAY —10 A.M children s ward and clinic 11 A M medical wards 2 P M , gynæcological operations, medical surgical and eye clinics 4 15 P.M Mr H P Gibb Demonstration of Eye Cases

THURSDAY —10 A M neurological and gynæcological clinics Noon fracture clinic. 2 P M , operations medical surgical and genito urinary and eye clinics 4 15 P.M Mr Edgley Curnock Aspects of Dentistry of Interest to the General Practitioner

FRIDAY —10 A.M. medical wards skin clinic Noon lecture on treatment 2 P M operations medical surgical and throat clinics 4 15 P M , Dr H W Post Demonstration of X Ray Films

SATURDAY —10 A M , children s and surgical clinic 11 A M medical wards

The lectures at 4 15 P M are open to all medical practitioners without fee

FELLOWSHIP OF MEDICINE AND POST GRADUATE MEDICAL ASSOCIATION 1 Wimpole street W

MONDAY Jan 18th to SATURDAY Jan 23rd —ST JOHN S HOSPITAL 5 Lisle street W C afternoon course in dermatology (open to non members) —NATIONAL TEMPERANCE HOSPITAL Hampstead road N W Tues 8 30 P M Mr R Y Paton Deformities Thurs 8 30 P M Mr C A Joll Thyroid —NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland street, W , all day course in cardiology (open to non members) —ST PETER S HOSPITAL Henrietta street W C , all day advanced course in urology —Courses arranged by the fellowship are open only to members

NATIONAL HOSPITAL Queen square, W C

MONDAY, Jan 18th.—3 30 P M Mr Elmquist Demonstration of Re educational Methods

TUESDAY —3 30 P M Dr Denny Brown The Nervous Control of the Sphincters

WEDNESDAY —3 30 P M. Dr Kinnier Wilson Clinical Demonstration

THURSDAY —3 30 P M. Dr Gordon Holmes Neurosyphilis (I)

FRIDAY —3 30 P M. Dr Walshe Disseminated Sclerosis (I)

Out patient clinic daily at 2 P M

LONDON SCHOOL OF DERMATOLOGY 5 Lisle street, W C

TUESDAY Jan 19th.—5 P M , Dr W Griffith Eczema.

WEDNESDAY —5 P M., Dr I Muende Histopathology

HOSPITAL FOR SICK CHILDREN Great Ormond street, W C

THURSDAY Jan 21st —1 P M Dr Ian Gordon Modern Therapy in the Anæmias of Childhood 3 P.M Mr A Simpson Smith Bleeding per Rectum

Out patient clinics daily at 10 A.M and ward visits at 2 P M

CENTRAL LONDON THROAT NOSE AND EAR HOSPITAL Gray s Inn road W C

FRIDAY Jan 22nd —4 P M , Mr N Asherson Pyrexia of Ear Nose and Throat Origin

ST JOHN CLINIC AND INSTITUTE OF PHYSICAL MEDICINE 42 Ranelagh road, S W

FRIDAY Jan 22nd.—4 30 P.M Dr E P Poulton Recent Serological Experiments in the Rheumatic Diseases.

LEEDS GENERAL INFIRMARY

TUESDAY, Jan 19th —3 30 P M., Mr Armitage The Surgical Treatment of Toxic Goitre

GLASGOW POST GRADUATE MEDICAL ASSOCIATION

WEDNESDAY Jan 20th.—4 15 P M. (Royal Infirmary), Mr Donald Duff Surgical Cases

Births, Marriages, and Deaths

BIRTHS

BROWN —On Jan 3rd at Penlea the wife of Dr J Brown of Bedlington of a son

EVERETT —On Jan 4th at Leominster the wife of Dr T F Everett of a daughter

HOLDEN TINCKER —On Jan 5th at Painswick the wife of Surg Lt Comdr R W Holden Tincker R N V R of a daughter

KIRWAN TAYLOR.—On Jan 6th at Cadogan square S W , the wife of Dr Gordon Kirwan Taylor of a daughter

LYNAGH —On Jan 3rd at Belfast the wife of Surg Lt -Comdr. T B Lynagh R.N of a daughter

MACLEOD —On Jan 3rd at 27, Welbeck street, W the wife of Mr Cameron MacLeod, F R C S , of a son

MITCHELL.—On Jan 4th at Gipsy Hill London S.E., the wife of Dr T Carlyle Mitchell, of a son

WILSON —On Jan 7th at Alexandra Park road, N , the wife of Dr G A Wilson, Tanganyika Medical Service, of a son.

MARRIAGES

MITCHELL—MCCALLUM.—On Dec. 31st at Umtali John C G Mitchell M B , Rhodesian Medical Service to Anne, youngest daughter of Mr Colin McCallum, Greenlaw, Berwickshire

PEENEY—PORTER —On Jan 4th at the Church of the Most Holy Redeemer, Chelsea Angelo Louis Peter Peeney M R C.S to Elisabeth Belle Porter B Sc. daughter of the late Geoffrey Porter, A M I C E of Worthing

WALLACE—WEATHERHEAD —On Jan 2nd at Chelsea Old Church Dr Hugh John Wallace to Dr Norah Ellen Weatherhead eldest daughter of the late Canon H T C Weatherhead of C M S , Uganda and Felstead

DEATHS

BREEKS —On Dec 31st at Broughton Craggs Cumberland Charles Wilkinson Breeks M B Edin , in his 67th year

RAND —On Jan 3rd at Brightlingsea Richard Frank Rand M D Edin F R C S Eng

RICHARDSON —On Jan 6th at Brookfield London N William Richardson M D Edin B Sc. (Pub Health) at the age of 80

SEMPLE.—On Jan 7th Lt Col Sir David Semple M D R.U.I. D.Sc Belf D P H Camb R.A M C

SWALLOW —On Jan 9th at East Grinstead, Sussex Alfred James Swallow M B Durh. formerly of Clapham Common aged 68

THACKRAH —On Jan 10th at Belsize Park-gardens Hampstead, N W Margaret Grace Thackrah B A Lond M D M R C P Lond

THOMPSON —On Jan 11th at Ellerdale road Hampstead N W Arthur Hugh Thompson M.D Camb M R C S Eng ophthalmic surgeon aged 77

TONKS —On Jan 8th at Chelsea Henry Tonks F R C S Eng, formerly Slade Professor of Fine Art in the University of London aged 74

N B —A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages and Deaths

NOTES, COMMENTS, AND ABSTRACTS

THE SUPPLY OF RADIUM

IT seems clear that the trend towards the use of larger radium units will result during the next few years in a demand for radium far beyond the financial resources of the National Radium Trust. This is the conclusion stated in the seventh annual report of the National Radium Trust and Radium Commission 1935–36 which has just been issued (H.M. Stationery Office, Cmd. 5342. 1s. 6*d*.). There was a prospect for a time that a further large stock of radium might form part of the national memorial to the late King George, but that prospect has not materialised. In the same report the Commission states that good progress has been made at almost all the national and regional centres. At some of them the volume of work has grown so as to require additional medical personnel and to make it possible to appoint a deputy for the radium officer when on leave or visiting other centres. *There is a gratifying tendency to include a* physicist in this personnel. Another direction in which growth is desirable is in the provision of pay beds at centres. Unless these are provided the middle-class section of the community is largely deprived of the opportunity of radiation treatment and the Commission is prepared to consider projects by which centres can use national radium for the treatment of patients in pay beds, up to 20 per cent of the whole bed provision. The Commission is also advocating a system of outpost centres in the various areas for the purposes of examination, diagnosis, and follow up. The need for such questing is emphasised by a calculation that of the 40 000 patients estimated to be suffering from cancer in accessible organs only about 8000 actually obtain radiation treatment. Delay in seeking assistance, it is suggested, is caused more by *fear of the treatment than* by ignorance and there is no doubt that surface radiation does away with many of the objections felt by patients to interstitial radiation. Radium beam treatment is, however, not only costly in time and material but cannot be more widely used without a substantial increase in the amount of radium available and this consideration is the basis of the Trust's statement that far more radium will shortly be required.

ALCOHOL AND MOTOR ACCIDENTS

AT a meeting of the Society for the Study of Inebriety held on Jan. 12th Dr. H. M. Vernon pointed out that though road traffic accidents have in the last two years, receded a little on the maximum observed in 1934 *the fatalities still average 18 a day* and the injuries over 600. The Ministry of Transport attributes more of the fatalities to pedestrians than to drivers, but estimates made in other countries assign from 67 to 80 per cent. of them to drivers.

THE SPEED FACTOR

Speed appears to be the most important cause of accidents and the Ministry of Transport considered that a fourth of the fatalities attributed to drivers in 1935 was due to excessive speed; but many of the other causes tabulated were due in some degree to this cause. The Ministry's data show that private cars and motor cycles incurred their largest proportion of accidents when travelling at a speed of 20 to 40 miles an hour whilst vans, lorries, and public conveyances incurred their largest proportion at a speed of 10 to 20 miles. As it is estimated that these latter vehicles travel 8 to 16 times further than motor cycles before causing a fatality and two to three times further than private cars it appears that there is a close relationship between speed and accidents. In Berlin it was found that when the speed limit for lorries and taxi-cabs was suspended, accidents increased two to threefold; but the rules governing the speed limit of private cars were not altered, and in their case accidents remained unchanged. Converse evidence was obtained in Rhode Island, U.S.A., for when the average speed was reduced from 37 to 31 miles per hour the fatalities were reduced 27 per cent.

The importance of the speed factor is emphasised because of its relation to the effects of alcohol consumption on drivers. The Committee of the British Medical Association on 'The Relation of Alcohol to Road Accidents' reported, in 1935, that 'very moderate quantities of alcohol (e.g. 3 oz. of whisky) had been shown by psychological tests to diminish attention and control and to reduce the rapidity and accuracy of coördination with which movements of the eyes, hands, and legs are made. The alcohol must therefore frequently affect the driving capacity of the driver.' It is evident that the adverse effects are more likely to lead to an accident the greater the speed of driving. The influence of a small error becomes *magnified in direct proportion* to the speed, whilst the distance within which a car can be pulled up when a pedestrian or other possible obstruction is seen varies with the square of the speed. The reaction time is increased 0·1 to 0·4 second and alcohol has the additional effect of causing drivers unconsciously to accelerate their speed. Tests made on twenty subjects by means of a motor driving apparatus showed that after drinking 2·8 oz. of whisky the rate of driving increased 0 per cent. on an average while the driving errors increased 13 per cent. An acceleration of the kind mentioned indicates the importance of all cars being compulsorily provided with a speedometer.

UNDER THE INFLUENCE OF——

The data adduced by the Ministry of Transport indicate that only 1 in 80 of the fatalities attributed to various road users were due to the persons concerned being obviously 'under the influence of drink or drugs,' but evidence from America suggests that alcohol plays a much larger part in motor accidents. It is stated that though alcohol is directly mentioned in only 7 to 10 per cent. of the fatal traffic accidents the traffic commissioners believe that probably a third or a fourth of the motor accidents are partly attributable to the consumption of alcohol by the drivers. A new method of obtaining evidence on this problem is now being investigated. It is based on the determination of the alcohol content of small samples of the blood or urine taken from the driver soon after an accident has been incurred.

Estimates made by several independent investigators showed that of the persons having 1·0 part of alcohol per 1000 in their blood from 40 to 63 per cent. were found to be 'under the influence'; of those with 1·7 parts from 80 to 88 per cent. were so affected and of those with 2·0 parts, the whole were so affected. As regard the blood analyses made on persons involved in motor and tram traffic accidents two Swedish investigators found that 33 out of the 113 persons tested had more than 1 part of alcohol per 1000 in their blood. An American investigator found that of 119 drivers involved in motor accidents, 11 had 1·4 to 3·6 parts of alcohol in the blood while 74 of them had more than 0·2 part. Analyses of the blood of 208 persons involved in traffic accidents in Munich showed that only 8 per cent. were practically alcohol free; 1 per cent. had 0·01 to 1·00 part; 39 per cent. had 1·01 to 2·00 part and 3 per cent. had 2·01 parts or more.

The frequency with which large amounts of alcohol were found in the blood in Munich was due to the police having compulsory powers for taking blood samples in cases of accident and apparently they exercise these powers only when they suspect alcohol as a causative factor. Persons with considerably less than 1 part of alcohol per 1000 in their blood may have their driving adversely affected even though they do not appear to be 'under the influence.'

for it is found that after drinking three ounces of whisky—which produces adverse effects in most persons—the blood is found to contain, as a maximum, 0 3 to 0 4 part of alcohol per 1000

The logical conclusion is that advanced by the *Times* in a leading article when it said, "As things stand at present there would appear to be no absolute safeguard for the motor driver but total abstinence" Such abstinence should be practiced several hours before driving, as well as during its course, owing to the slowness with which alcohol disappears from the blood

THE RED CROSS IN SPAIN

A MEMORANDUM from the International Red Cross Committee at Geneva states that 35 national red cross societies have now contributed to the relief of sufferers in the Spanish civil war, their donations amounting to 459,398 Swiss francs, of which over 330,000 francs has come from South America These gifts are administered by the International Committee with impartiality, and the sums received have made it possible for medical supplies for the treatment of wounded, on both sides, to be sent in increasing quantities Information bureaux have been established at a number of centres, and delegates of the International Committee are working at Madrid, Valencia, Barcelona, Burgos, Santander, Bilbao, San Sebastian, Alicante, Seville, Saragossa, and Palma de Majorca The Committee's delegates have been authorised nearly everywhere to visit the prisons, and agreements have been established whereby the release of women, children, boys under 18, adults over 60, and invalids has been secured Arrangements for the future care of orphans are in train The delegates have encountered a promising spirit of coöperation on both sides, but a good many difficulties arise in carrying out the letter of the agreements Unfortunately certain commodities, such as coal, are already scarce in Spain, food rationing is being instituted, and the question whether the Red Cross can undertake the supply of a minimum of the necessities of life to women, children, invalids, and prisoners is under consideration. The sums required would far exceed those received up to the present, and so far the most that can be attempted is the supply of a few parcels of food and condensed milk to sick prisoners

Donations to the Red Cross Spanish Relief Fund may be sent to the director-general of the British Red Cross Society, 14, Grosvenor-crescent, London, S W 1

Messrs E MERCK, of Darmstadt, manufacturers of chemicals and medicinal specialties, announce that the selling rights for their preparations in the United Kingdom and Irish Free State are now in the hands of Messrs Savory and Moore Ltd of 61, Welbeck-street, London, W 1 Their publicity department, established in this country for the convenience of medical practitioners wanting information and samples of the Merck products, has been moved to 60, Welbeck-street, W 1, and requests should still be directed to this office

SURGICAL TREATMENT OF CARDIAC ISCHÆMIA*

BY LAURENCE O SHAUGHNESSY M.D Durh
F R C S Eng

HON CONSULTANT TO THE LAMBETH CARDIOVASCULAR CLINIC (LONDON COUNTY COUNCIL) AND CONSULTING AND THORACIC SURGEON TO THE BRITISH LEGION SANATORIUM PRESTON HALL, AND TO THE NOTTINGHAMSHIRE COUNTY COUNCIL

With an Introduction by

Viscount DAWSON OF PENN P R C.P Lond

Introduction

(LORD DAWSON)

IT is only natural to suppose that a muscle which is unceasingly active from its birth to its death and which shows a large and quickly varying range in its output of energy must have provision for a large blood-supply and be sensitive to deficiencies thereof

In fact the healthy heart muscle *has* this capacious blood-supply for it is calculated that during exercise the flow of blood through the coronary arteries per minute is 1 4 litres, which is over three times the volume of the heart. Again, if there is a 50 per cent. fall in oxygen saturation of arterial blood the coronary flow may in compensation increase fourfold.

An organ so abundantly active, if it is to preserve its function and healthy structure, must be secured adequate nourishment. Absence of that nourishment will produce similar areas of degeneration in the myocardium whether narrowed arterial channels make quantity of blood inadequate, or inadequacy of oxygen content makes the quality of blood defective. Thus Büchner reduced the oxygen carrying capacity of the blood in rabbits by bleeding or by inducing a state of carbon monoxide poisoning At the autopsies multiple areas of necrosis were scattered throughout the myocardium, a finding resembling that present after coronary obstruction in man Or again when Kountz and Hamouda perfused the isolated dog's heart with venous blood the resulting oxygen starvation gave electrocardiographic tracings from that heart resembling those of coronary occlusion

Turning to the evidence of clinical records Büchner Weber, and Hanger have published 43 fatal cases of cardiac ischæmia. These comprise failure of blood supply by (1) coronary thrombosis in an apparently normal coronary tree (2) thrombosis complicating atheroma of the coronary arteries (3) rigidity and narrowing of the arteries of the coronary tree without gross obstruction and (4) syphilitic aortitis when only the orifices of the coronary arteries were affected In all these cases there were alike the characteristic electrocardiogram and at autopsy the characteristic pathological changes in the myocardium—viz with obstruction of a main coronary artery there was an old or recent infarct while with no actual block but a general narrowing of the arterial channels there were scattered areas of recent necrosis or old fibrosis.

In cases therefore where occlusion is not immediately destructive of life, the problem is to secure an adequate compensatory circulation to the myocardium The difficulty is not that the anastomoses are incapable of development but rather that the vascular needs of the myocardium are so great.

Spalteholz has demonstrated a rich anastomosis between the right and left coronary trees and between the branches of the same artery but the effectiveness of these and the capillary beds they feed would be impaired in some cases of arterio sclerosis There are further anastomoses between the coronary tree and the vasa vasorum of the aorta and pulmonary artery but how far this network of collateral vessels is effective in surviving cases of coronary occlusion is not known. On the other hand it is known that pericardial adhesions can form an effective collateral circulation But the existence of such adhesions in a case of coronary occlusion is a chance and uncommon happening Thus in Parkinson and Bedford's 83 autopsies on cases of coronary occlusion there were 11 cases of pericarditis

The vascular effectiveness of such adhesions is demonstrated by a striking case published by Thorel. The patient died of carcinoma and the post mortem showed an old adhesive pericarditis side by side with a complete and long standing obliteration of the main stems of both left and right coronary arteries There had been no history of cardiac distress during life For a long period the myocardium must have had its supply from this collateral circulation

Moritz by injection studies has been able to establish the existence of vascular connexion through these adhesions between the pericardium and coronary tree

It follows therefore that in a considerable coronary occlusion collateral circulation must eventuate if the myocardium is to be saved Such a compensatory circulation can form of itself; where it does not do so the use of surgical means to establish it is essentially reasonable and its prospect should be good in carefully selected cases provided the capillary bed itself is not too degenerate to profit by a renewed arterial supply

---

Experimental Relief of Cardiac Ischæmia

VARIOUS ingenious methods have been used to produce ischæmia in the heart of the experimental animal. The most ingenious were perhaps those of Vogt (1904) who injected lycopodium seeds in a fluid suspension down the carotid artery with sufficient force to close the semilunar valves and drive the seeds into the coronary circuit Ligature of various *branches of the coronary artery is of course a much* older experiment and it has been found that like man the animal will usually survive occlusion of a main trunk more especially ligature of the descending branch of the left coronary True there remains an infarct and in the period of acute ischæmia the heart is very sensitive so that some chance stimulation may produce a fatal fibrillation but serious after-effects do not usually appear Ligature of the right coronary artery is a rather more severe operation and ligature of the left coronary before it has given off its circumflex branch *is fatal*

Leriche and Fontaine have lately made important contributions to the experimental study of coronary occlusion They found that the perivascular nervous plexus of the coronary vessels played a significant part in the reaction of the mammalian heart to coronary ligature A preliminary injection of the perivascular plexus diminished the risk of ventricular fibrillation and enabled the animal to maintain a blood pressure adequate for the best use of the normal collateral channels Further, they claimed that excision of the neighbouring ganglia favoured the formation of a good collateral supply, as they had shown to be the case in experimental occlusion of the vessels of the lower limb It is true that there is an important school who would attribute all coronary vasoconstrictor effects to the vagus and not to the sympathetic The exact experiments of Rein, using his "stromuhr" and making his observations on the intact animal, seemed indeed to demonstrate this point quite clearly, but in the present uncertainty as to the exact morphology of the autonomic nervous system this is only typical of the inconsistencies with which the literature of the system abounds

---

* A special lecture introduced by Lord Dawson delivered before the Royal College of Surgeons of England on Jan 15th 1937 Lord Dawson spoke as head of the cardiovascular clinic at Lambeth Hospital where the clinical work described by Mr O'Shaughnessy is being done.

Leriche and Fontaine were also attracted to the possibilities of operation on cardiac aneurysm and for this purpose employed a free graft of the pectoralis muscle (1932)

In 1935 Beck and Tichy published the results of some animal experiments in which various grafts fashioned from the fibrous pericardium, muscles of the chest wall and omentum were applied to the surface of the heart, after preliminary destruction of the epicardial endothelium The method and results of these experiments were not recorded, but they described some other experiments in which a large area of epicardium was removed so that massive adhesions formed between the heart and the parietal pericardium these animals were able to withstand almost complete occlusion of both main coronary trunks, which was effected by means of silver bands

My own experiments on cardiac grafting were proceeding at the same time as the work recorded by Beck, the first omental graft being performed at Downe in the spring of 1933, but while Beck was stimulated by Moritz's work on vascularisation of pericardial adhesions, my own experiments had their origin in some earlier work on resection of the thoracic œsophagus, when the valuable properties of a pedicled omental graft first became apparent to me I had also been encouraged to repeat some of the Leriche experiments on ligature of the coronary artery using control of the nervous factor, and I was aware of the earlier observations of Klose (1922), who had noted the capacity of free grafts of omentum to replace excised portions of parietal pericardium

In a previous paper (1936) I have described the first results of a series of omental grafts in the cat and the greyhound These demonstrated that the presence of such a graft is compatible with the highest degree of physical exertion Greyhounds which had suffered ligature of the descending branch of the left coronary artery chased the electric hare round a full course (525 yards) without distress after the operation of cardio omentopexy

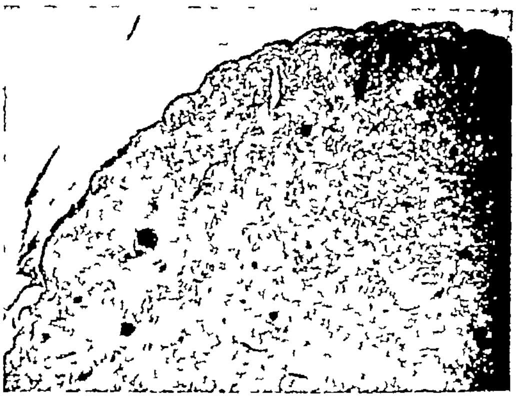

FIG 2—Section of myocardium of cat showing pigment injected through an omental graft (× 50)

To demonstrate the existence of vascular connexions between the graft and the heart of the animal, the organ was removed from the chest by severing all the great vessels and was suspended to a retort-stand, leaving the graft as its sole connexion to the animal The abdominal aorta was cannulated and the injection fluid (in most cases a watery suspension of Indian ink but in others a coarse injection medium composed of starch, carmine, and gelatin) was delivered at a pressure of 120 mm of Hg In these conditions the fluid was seen to fill the coronary tree until it appeared in the cavity of the heart and dripped out from the cut ends of the aorta and pulmonary artery (Fig 1) The injected material was visible to the naked eye, and in microscopical sections could be demonstrated lying in the deeper branches of the coronary artery even under the endocardium (Fig 2)

It is important to emphasise that vascularisation occurred whether the graft was applied to a normal heart to a recent infarct, or to an old infarct, for these are the three possible choices with which one might be presented when operating for the relief of cardiac ischæmia in man. It must also be stressed (in view of one recent criticism) that when the graft was applied to an infarct general connexions were established through the infarcted area with the remainder of the coronary tree The graft was always so applied to the apex of the heart as to overlap the territories supplied by the right and by the left coronary arteries

During the past year further experimental evidence of the vascularisation power of the cardio omental graft has

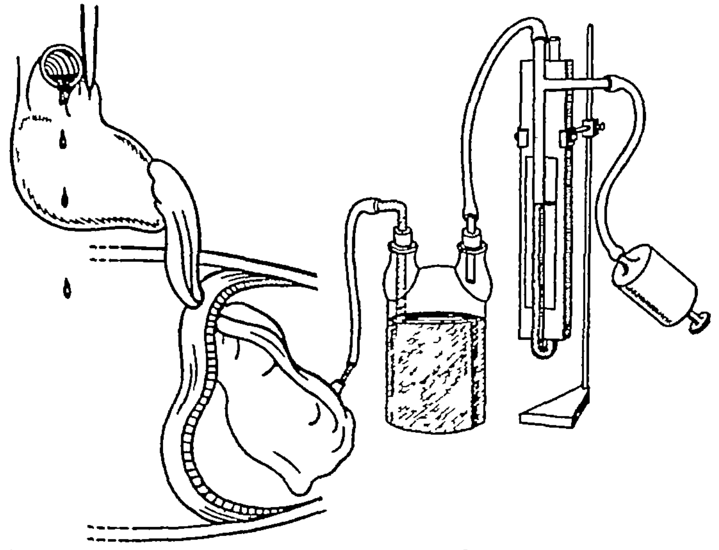

FIG 1.—Injection of blood through an omental graft into the heart to demonstrate the vascular connexion

accumulated and some of the more important findings will now be summarised.

1 *Histological evidence without the use of injection* —On examining the heart a week after application of the graft a very large primitive vessel could be seen growing into the myocardium (Fig 3)

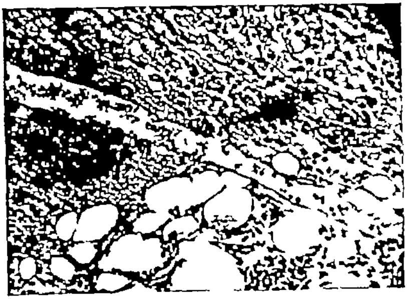

FIG 3.—Section through junction between myocardium (above) and omentum (below) a week after operation A large primitive vessel is growing from the omentum into the heart muscle. (× 1 0)

2 *Biological evidence of the protective function of the omentum* —In an experiment performed by Mr George Mason (details of which will be published later) a diaphragmatic graft was applied to the surface of the heart after ligature of some branches of the coronary vessels The animal was killed some months afterwards and it was then discovered that the omentum had made its way through a small defect left at the base of the diaphragmatic flap and had firmly attached itself to the ischæmic area in the wall of the heart.

3 *A long-term experiment* —On Dec 8th 1936 there was killed a greyhound which had been subjected to ligature of the descending branch of the left coronary artery on March 21st 1935 He had a cardio-omentopexy on May 28th, 1935 and on Sept 12th, 1935 there is the note Exercise tolerance tested on track. Running capacity normal run finished in very good order The appearance of the heart is shown in Fig 4 There was an extraordinary vascularity of the mediastinum and there were numerous vascular connexions between the graft and the anterior mediastinum Anastomoses could also be seen between the vessels of the diaphragm and the base of the graft The heart was then removed from the chest and an injection carried out in the usual way using a barium emulsion Complete filling of the coronary tree was obtained and on the radiogram the injected trunk of the left coronary artery could be seen.

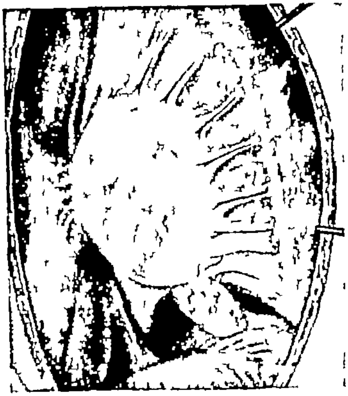

FIG 4 —Dissection of thorax of a greyhound eighteen months after cardio-omentopexy showing vascularity of mediastinum and vascular connexions between graft and mediastinum

* * * *

The omentum is the only structure in the body with the specific property of vascularisation and many years ago Rutherford Morison recognised the practical importance of this fact The only uterine fibroids which can attain to colossal size are either retroperitoneal or depend chiefly upon vessels derived from the omentum for their continued growth The largest I ever removed was of the subperitoneal variety It had a thin and narrow pedicle below but above was capped by omentum which carried to it at least half a dozen arteries of the size of the brachial.

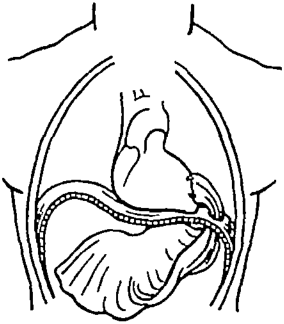

FIG 5 —Diagram illustrating cardio-omentopexy in man

In its inventor's hands and in those of his immediate successors omentopexy proved a useful operation for selected cases of cirrhosis of the liver Prof Grey Turner is still in touch with a patient who has remained well since his operation in 1906. Personal experience of it in the Sudan confirmed my belief in its value provided Morison's exact technique was followed and the choice of case was correct More recently the therapeutic value of omentopexy in cirrhosis has been questioned, but all authorities are agreed as to the remarkable vascularising powers of the organ even Hughson who condemns it as treatment for cirrhosis, agrees on this point and quotes the Mayos and other surgeons of experience to the same effect. Thus even if it is conceded that omentopexy cannot cure cirrhosis of the liver—a condition whose ætiology and pathology remain after all, to a large extent obscure—the essential theoretical basis of cardio-omentopexy (Fig 5) remains unshaken Apart altogether from the clinical experiences of Rutherford Morison Sir David Wilkie's early and complete experiments on the omentum gave an initial impetus to its use in the surgery of the chest. Wilkie showed how in the cat the omentum could avert the disaster which normally follows ligature of all the vessels to the spleen and there seemed no reason why if the omentum could compensate for acute ischæmia in its natural milieu it should not fulfil a similar function once it gained access to the thoracic cavity

Cardio-omentopexy in Man

The school of thoracic surgery to which I belong has always held that major operations on the chest are only justifiable, and only successful, when there is full collaboration between physician and surgeon It is not enough for the physician to refer a case, he must be in close contact with the patient just before the operation and must indeed help to select the time for it, and he and the surgeon must share the conduct of the post operative treatment The recent development of radiological and other special methods of examination have done nothing to invalidate this principle, and it is of course of special importance before operation is performed on the human heart I should like to emphasise that although the operation of cardio omentopexy was devised in a surgical laboratory and its technique has been modified according to purely surgical contingencies, I have performed it only after careful consultations with the medical staff of the Lambeth Cardiovascular Clinic (Lord Dawson of Penn, Dr Daniel T Davies, and Dr H E Mansell) In addition the suitability of each patient for general anæsthesia has been assessed by Dr J K Hasler, whose advice and assistance have been available at each operation The elimination of post operative shock has been made possible by experimental work done in the laboratories of the Royal College of Surgeons, but the successful conduct of the ten days following operation has depended on unremitting medical care

ALTERNATIVE OPERATIONS

Before describing the way in which a graft may assist in recovery from cardiac ischæmia, it is perhaps necessary to refer to some alternative procedures In all cases of cardiac ischæmia there is probably a vasospastic factor, and this is of special importance in diffuse atheroma of the tree—as is suggested by the beneficial effect of the nitrites in angina of this type It therefore appears logical to attempt to influence this spasm by nerve section, and the evidence in favour of *sympathectomy* has been summarised by Leriche (1935)

In the past (1926–31) I have from time to time carried out sympathectomy, but more recently, when an intervention on the nervous side was indicated, I have used the Mandl technique of *paravertebral injection* This operation proved most successful in the case of a man of 78, whom I discovered as a bed ridden patient with frequent anginal attacks and who was afterwards able to resume a normal life of such activity as was compatible with his age At the same time, he has continued to have attacks of faintness, and these attacks he describes as essentially similar to his old attacks, with, for him, the important difference that they are painless Experience of this case finally freed me from the old bogy that it was wrong to remove the warning signal (the "red light" of Mackenzie) of pain in the angina of effort, the patient still receives the warning if he attempts too great exertion, but the removal of the pain has been in every way beneficial. This case also confirmed me in my belief that attempts to remove the nervous factor should be reserved for patients whose age or general condition precluded a direct attack on the ischæmic factor It is established that fatal angina occurs only when there is definite and gross disease of the coronary tree, and it seems reasonable to assume that if a new blood supply can be furnished the effect of spasm of the diseased vessels will lose its significance, and if, as now seems probable, the seat of the pain is the anoxæmic myocardium, pain should be abolished and cardiac efficiency maintained. So far as we can tell from our initial cases, the graft does seem to have this effect, although the possibility that in certain patients the nervous factor may also require control cannot yet be excluded

Another indirect operation of extraordinary interest is *total thyroidectomy*, first performed for the relief of congestive heart failure by Cutler in 1932 Since then several series have been published both in America and in this country, and Levine states that the immediate mortality is between 5 and 10 per cent Undoubtedly this operation has been an important contribution to cardiovascular surgery and it should encourage further efforts to influence incurable cardiovascular disease through the endocrine system.

DEATH FROM CARDIAC ISCHÆMIA

Cardiac ischæmia can cause death in various ways, some of which must be considered in relation to cardio omentopexy The mechanism of some deaths—e g, rupture of the heart into the pericardial sac—is quite clear, that of others is less so

Of special interest in a general way, although not of course immediately related to treatment by grafting, are those cases in which sudden death follows occlusion of some quite small branch of the coronary tree and is presumably caused by the operation of some nervous reflex It seems probable that the mode of death is similar to that sometimes seen in pulmonary embolism when the embolus has been too small to have any significant effect on the mechanical efficiency of the pulmonary circulation. The shock associated with sudden occlusion of a larger vessel may also prove fatal, especially if morphia in adequate dosage is not given

The mode of death in those comparatively rare cases of coronary thrombosis in which rupture of the infarct occurs soon after the occlusion is clear either the immediate collateral supply has been inadequate or, more probably, an extension of the thrombotic process has limited access of collaterals to the ischæmic area The course of other cases in which a state of permanent cardiac inefficiency follows an initial vascular catastrophe, whether the inefficiency be marked by swelling of the feet and enlargement of the liver, by recurrent attacks of acute respiratory distress, or by persistent angina of effort, may be explained on the basis of a myocardial blood supply sufficient to maintain life but insufficient for normal cardiac function The fact that the infarct following coronary thrombosis often involves the deeper layers of the myocardium together with the endocardium explains the source of the peripheral emboli, either pulmonary or systemic in distribution, which are one of the more serious complications of acute cardiac ischæmia The myocardial failure of syphilitic aortitis, although frequently sudden in its fatal ending, is commonly marked by a period of recurrent angina of effort, and the mechanism of the gradual strangulation of the coronary supply at its source is in the main comprehensible More mysterious are the factors which determine an eventual failure of the ischæmic heart in chronic hypertension, for often the attendant circumstances of a fatal attack of heart failure do not at first differ from those of attacks which have in the past been survived, nor do the gross or microscopic appearances of the heart at autopsy appear inconsistent with continued survival. Goldenberg and Rothberger have shown that the perfusion coefficient is lowered in the hypertensive heart and their work is a useful reminder that functional as well as morphological methods may be employed in the estimation of cardiac ischæmia.

FUNCTION OF THE GRAFT IN VARIOUS DISORDERS

FIG 6.—Diagram to show the function of the graft in coronary obstruction and coronary insufficiency

The interest of the surgeon is of course specially directed towards *cardiac aneurysm*—one of the less common sequelæ of acute cardiac ischæmia—and this interest has naturally been more general since Sauerbruch's astonishing success with radical operation for the condition Although aneurysm of the heart is rare—Huchard in the course of his career is said to have observed only three cases—its rarity must not be exaggerated for in one year alone three cases came to autopsy in Lambeth Hospital and in 1934 Steel reported its intra vitam diagnosis in six patients An aneurysm of the heart is the clearest evidence that the heart has suffered a grave vascular catastrophe, and although adherence of the sac to the parietal pericardium may enable some years of useful life to be passed life is eventually threatened for a second vascular occlusion may either so limit the blood-supply of the remaining cardiac muscle as to render it inefficient or produce a local necrosis of the aneurysmal sac which then perforates It is well to emphasise that while bodily activity may predispose to acute rupture of the heart after coronary thrombosis perforation of an aneurysm of the heart is due to a second vascular occlusion and *not* to some additional strain In the last case I observed the perforation occurred with the patient quite quietly resting in bed as she had done since her initial thrombosis some two months previously

In this case the sac of the aneurysm had failed to adhere to the pericardium and this was also the condition in another aneurysm I observed in which the patient died of progressive heart failure a few months after her initial thrombosis The fate of these two patients is in striking contrast to the favourable immediate course when parietal adhesions give access to an additional collateral supply: the historical case of Sternberg (who coined the term pericarditis epistenocardica) the case of Fugiami and the case reported by Koch and Kong may be cited

The graft as we have demonstrated on animals operates in several ways Not only is a new blood supply brought into direct relationship with the ischæmic area and with the coronary tree but the normal collaterals in the mediastinum are both reinforced and given access to the ischæmic heart This second function of the graft appears more important in man than in the animal for the vessels surrounding the pericardium seem in proportion larger As an example of this I would instance the inferior sternopericardial ligament (shown in Fig 9) which in the living patient appears as a much more important structure than studies in the cadaver would lead one to suppose Many vessels ramify in the subpleural fat which covers this ligament which is of course, so placed as to provide an immediate collateral supply through the pericardium when a superficial infarct occurs at the site of election which is on the anterior aspect of the organ in the region of the apex. At operation the graft is always arranged in such a way that adhesion with this ligament may develop A third function of the graft which Beck has recently emphasised is its bridge action in supplementing the natural anastomosis between the right and left coronary arteries

It is obvious that deaths during the acute stage of *coronary occlusion* either from general heart failure—probably in most cases a ventricular fibrillation—or from perforation of an infarct cannot be avoided by means of a graft and it is only when the patient has survived these immediate perils that he can be considered as a possible subject and of course only then if it appears that the natural processes of repair have been inadequate

In every case of coronary thrombosis the fact must be faced that a second attack is almost inevitable and although under favourable conditions this may be postponed for years the exact time of its coming cannot be predicted. It is also clear that recovery from a second attack is only likely if natural repair and compensation for the first attack have been efficient and the provision of an alternative blood supply would be especially valuable when after an attack of coronary thrombosis natural compensation has been inadequate Under these conditions the provision of an additional blood supply would serve two purposes In the first place better nutrition of the still functioning myocardium might improve its performance and in the second place once the heart was in possession of an alternative supply the accident of a second vascular occlusion should be less likely to be fatal

The factors governing the onset of *ventricular fibrillation* in a heart containing an old fibrosed infarct are most mysterious and as several authorities have pointed out autopsy often reveals no mechanical cause for the fatality—indeed from the post mortem appearances the accident might just as well have occurred months previously or not at all It is possible that these circumstances might provoke the ideal indication for operation on the autonomic nervous system, at present the one certain factor is the ischæmia, and control of this factor might prevent deaths from ventricular fibrillation.

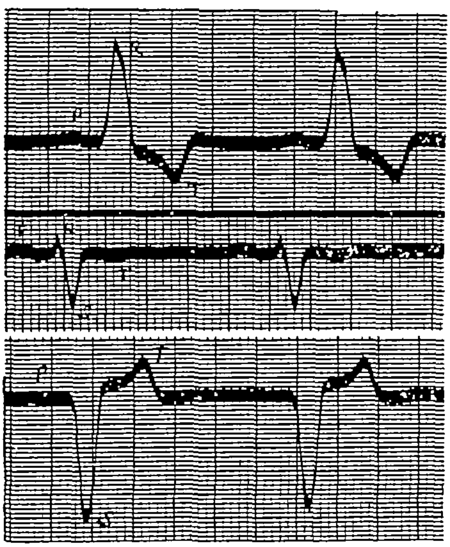

FIG 7 (Case 5)—Electrocardiogram taken before operation showing myocardial degeneration

Mention has been made of the *embolic complications* of coronary thrombosis These sometimes occur early in the illness and cannot be influenced by grafting, but as presumably the efficient organisation of the deeper layers of the infarct is the only protection against the detachment of emboli and this organisation in turn depends on the efficiency of the natural collateral channels, a graft might serve a useful function in some of the delayed cases

In cardiac aneurysm the function of the graft would be to supplement the myocardial blood-supply sufficiently to make a second occlusion less serious, and anastomosis with the sac of the aneurysm should serve as a protection against perforation

On theoretical grounds a graft might be of special service in the case of cardiac ischæmia resulting from an established *syphilitic aortitis*, for here, as has been already mentioned, all the natural processes of compensation are at a disadvantage and there is a normal peripheral tree into which the new blood-supply can be fed

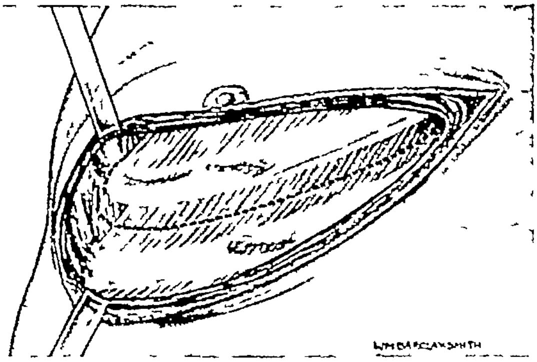

FIG 8—Division of costal cartilages

The provision of an additional blood supply to a heart with *diffuse atheroma of the coronary tree* but no gross obstruction has attractive possibilities It has been demonstrated by Büchner in several fatal cases of hypertensive heart failure that an electrocardiogram characteristic of ischæmia was associated with diffuse areas of necrosis in the heart after death, and for such patients an additional blood supply should be beneficial.

INDICATIONS

It will be seen that the indications for cardio-omentopexy are not yet rigidly defined. They will be more fully described in a future paper by the medical staff of the Lambeth Cardiovascular Clinic, and here only a provisional outline will be given. We have been guided in each individual case by two considerations In the first place we have demanded unequivocal evidence of cardiac ischæmia, and we have then proceeded to an intervention only when we have been satisfied that its immediate risks were less than the patient must in any event run if his disease pursued its natural course These points may be illustrated by reference to some of the patients submitted to operation In Case 1, for example, the patient had had a coronary thrombosis a year previously and he was left with such serious angina of effort that he had to stay in hospital. It seemed clear that the effect of a second occlusion would prove very serious and probably fatal. In Case 3 the patient who had hypertension, suffered a coronary thrombosis, and in spite of rest and medical measures was eventually left with pulsus alternans, a gallop rhythm, and inability to rest lying down. It was unlikely that she would react favourably to another vascular crisis and her cardiac blood supply was therefore augmented by surgical means In Case 5 we had evidence on the electrocardiogram of gross myocardial degeneration (Fig 7), the patient had been bedridden for over a year and angina appeared on the slightest exertion Here too it seemed that further occlusion of the coronary tree would have serious consequences, which might be alleviated by a graft, and while it seemed unlikely that the well established pathological changes in the conduction system could be modified it seemed worth improving the nutrition of her still functioning myocardium

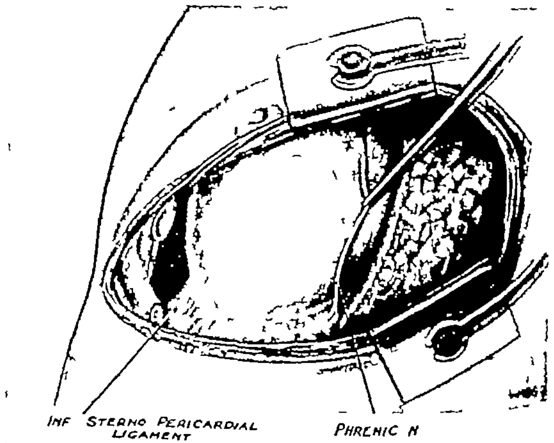

FIG 9—Exposure of pericardium and crushing of phrenic nerve.

TECHNIQUE

After suitable premedication, general anæsthesia is induced and maintained with the Tiegel Henle apparatus, which supplies oxygen under positive pressure together with vaporised ether With the patient on his back, the chest is entered through an incision along the fifth intercostal space which extends from the midline to the anterior axillary line The fifth and sixth costal cartilages are divided near the sternum after the manner of Kirschner (Fig 8) and by the use of a large Sauerbruch intercostal retractor the pericardium is exposed (Fig 9) The phrenic nerve is identified and crushed with a hæmostat and once this has been done the pressure in the anæsthetic apparatus is reduced (from 10 to 6 cm of water) and the table is tilted to the right As a result of these manœuvres the left leaf of the diaphragm appears in the operation field and after the insertion of two sutures the muscle is incised (Fig 10) The abdomen is then explored through the diaphragmatic incision a suitable portion of the omentum is obtained and brought through into the chest. The wound in the diaphragm is then closed by suture (Fig 11) The table is brought back to its original position the degree of inflation of the lung is again increased and the heart covered by the pericardium is once more in view With caution the pericardium is incised (Fig 12) and the graft is attached to the surface of the heart and to the edges of the pericardium by suture with fine linen thread (Fig 13) Finally the chest wound is closed in layers in the usual way (Fig 14) The appearance of the healed incision is illustrated in Fig 15 (Case 4)

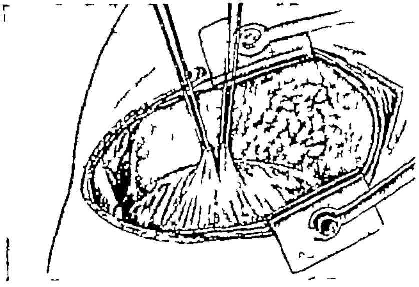

FIG. 10.—Incision through diaphragm

CASE HISTORIES

CASE 1 —A man aged 64 was suffering from angina pectoris dating from an acute illness diagnosed as coronary thrombosis for which he had been treated in a voluntary hospital Dr G W Pickering kindly saw the patient and confirmed the diagnosis of angina of effort On Jan 4th 1930 at Lewisham Hospital cardio-omentopexy was performed with the assistance of Dr Humphrey Nockolds and Mr A Simpson Smith, under general anæsthesia given by Dr Hasler There was no post-operative shock an hour after operation the blood pressure was 130 the pulse-rate 84 the respirations 24 and the temperature normal. No special cause for anxiety arose until Jan 10th when there was a severe melæna with collapse Transfusion was contemplated but not carried out and a second severe hæmorrhage on Jan 12th proved rapidly fatal At autopsy the source of the hæmorrhage was found to be a large chronic duodenal ulcer the colon and other abdominal viscera were normal. All was in order in the operation area and there was evidence of cardiac ischæmia especially of the right heart

CASE 2 —A man aged 65 a cosmopolitan of varying occupations. Angina pectoris for four years nine attacks in all Last attack on July 6th 1930 lasted four hours and was not relieved by amyl nitrite Admitted on the following day to St Stephen's Hospital (L C C), and transferred to the clinic on July 28th He was a heavy smoker until three years ago He gave a history of malaria and three laparotomies—for appendicitis adhesions and gastro-enterostomy A paternal uncle had dropped dead of angina Examination: slight tortuosity of radial artery heart normal clinically but enlarged radiographically; B P (blood pressure) 110/72; blood urea 32 mg per 100 c cm Wassermann reaction negative Electrocardiogram showed ST interval raised in leads II and III.

Cardio-omentopexy was performed at Lambeth Hospital on August 17th 1930 with the assistance of Mr F Watson and Dr P Berry under general anæsthesia given by Dr Hasler No difficulty in obtaining omentum in spite of previous laparotomies Pulse rate at the end of operation 96 Recovery was uneventful except for an immediate mild bronchitis He was kept in bed for 4 weeks and took his discharge on Dec 11th 16½ weeks after operation free of symptoms except slight breathlessness on exertion He had no more attacks of angina, his pulse improved in volume his blood pressure rose gradually to 160/90 and there were progressive changes in the electrocardiogram Slight movement of the left diaphragm were observed on the screen for first time 14 weeks after operation

CASE 3 —A man aged 71 retired from Burma police Angina pectoris for 2–3 years Attacks now almost daily related to exertion emotion or nightmare and relieved by tablets of nitroglycerin He was referred to the clinic by Dr Dean Pollard of Bedford and was admitted on July 27th 1930 Examination: oral sepsis, radial arterio-sclerosis heart enlarged clinically and radiographically; B P 205/105; blood urea 44 mg per 100 c.cm.; Wassermann reaction negative; electrocardiogram showed left ventricular preponderance T wave negative in lead I and ST interval depressed in lead I and *raised in lead III*

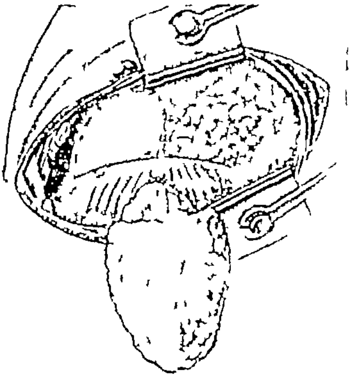

FIG. 11 —The graft drawn through the opening in the diaphragm

Cardio-omentopexy was performed at Lambeth Hospital on Sept 25th 1930 with the assistance of Dr H I Mansell and Dr W K Targett under general anæsthesia given by Dr Hasler Pericardium found stretched over an obviously hypertrophied heart At the end of operation the pulse-rate was 72 the B P [illegible] and the electrocardiogram showed no change After purulent bronchitis for a week recovery was uneventful Three anginal attacks occurred during first 3 weeks and none subsequently He was allowed up 4 weeks after operation and was discharged home at his own request 10 days later The electrocardiogram still showed no change For 4 weeks at home he showed progressive improvement with increasing activity and freedom from pain Symptoms of uræmia then appeared; he was readmitted a fortnight later and

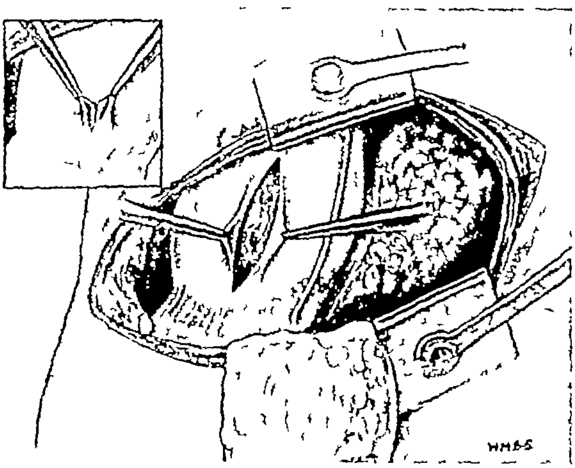

FIG 12 —Incision of pericardium

died on Dec 28th, three months after operation On readmission there was no evidence of heart failure and no anginal pain, in spite of violent hyperpnœa in Cheyne Stokes breathing The B P was 140/100, and the electro cardiogram showed considerable increase in voltage The blood urea was 116 mg per 100 c cm

Post-mortem findings—The abdomen contained an excess of free fluid, but the viscera, including the colon, were normal, and the graft could be seen in place passing through the diaphragm The kidneys showed chronic interstitial nephritis, and there was advanced atheroma of the abdominal aorta The wound in the chest wall was firmly healed and there had been complete restitution of the thoracic cage The right pleura contained free fluid in excess but the lung was normal The lower lobe of the left lung was collapsed, and there was atrophy of the left leaf of the diaphragm The graft was firmly attached to the heart, and after removal of the viscera injection of a watery suspension of Indian ink was carried out from the abdominal aorta A pressure of 100 mm Hg was employed, and the technique was identical with that used in the experimental series (Fig 1) A very profuse injection of the parietal pericardium was obtained, and ink eventually reached the chambers of the heart The specimen was fixed in formalin, and on section it was possible to see the ink lying in the myocardium There was diffuse fibrosis throughout the heart but time has not allowed of complete histological examination

CASE 4 —A woman, aged 44, a paper seller Admitted to Lambeth Hospital on March 5th, 1936, with the story that she had collapsed in the street five weeks before with pain under the heart She took to her bed for three days She had been breathless on exertion for a fortnight before the attack, and had since noticed increasing cough and breathlessness and a "stitch in the heart on hurrying" Findings on admission afebrile, cya and dyspnœic, gross oral sepsis, heart enlarged tachycardia and gallop rhythm, B P 200/140, râles, liver palpable, no œdema, electrocardi showed inversion of T wave in all leads, Wasser reaction negative A diagnosis of coronary thron and hypertension was made

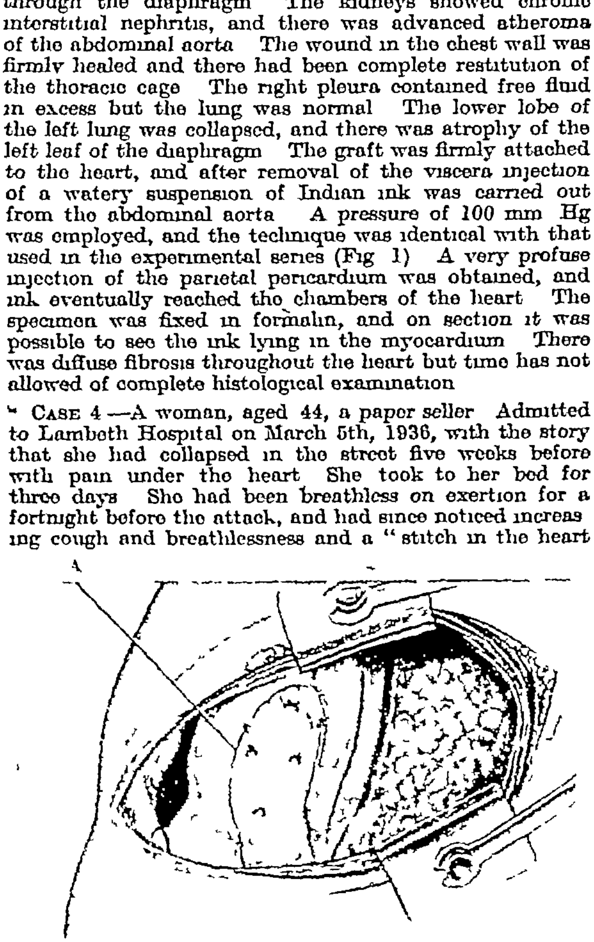

FIG 13 —The graft sutured to the pericardium (A = cut edge

In spite of rest in bed progressive heart failure o and on July 10th, four months after admission, exa tion showed heart grossly enlarged clinically and graphically, gallop rhythm unchanged, B.P 170 venous blood pressure 270/280 mm of saline, basal and a small pleural effusion on left side, liver enlarged, ascites, much œdema of legs and l region, inversion of T wave of electrocardiogram as b From this date she gradually improved The abd was tapped twice, and caffeine, digitalis, and Sal were administered In September all her teeth extracted. On Oct 1st, seven months after adm she was up two hours daily, and symptom free exce slight dyspnœa on exertion Gums well healed, not enlarged clinically, a radiogram showing rema decrease in its transverse diameter, gallop rh unchanged, definite pulsus alternans, confirme sphygmomanometer, B P 210–190/120, venous pressure 160–165, pleural rub at left base, b

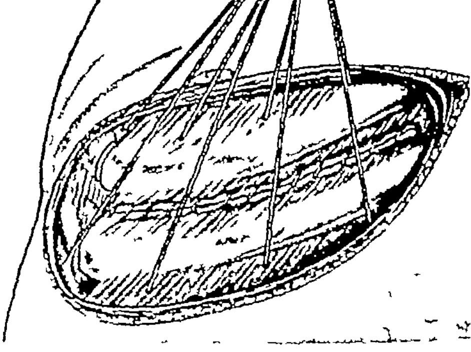

FIG 14 —Closure of chest wound

râles, liver edge just palpable, no ascites or œd increase of voltage and less inversion of T wa electrocardiogram

Cardio omentopexy was performed at Lambeth Ho on Oct 2nd, 1936, with the assistance of Dr Mansel Dr W H. Gabb under general anæsthesia by Dr H Aleuronat injected into pericardium At the end o operation the pulse rate varied from 100 to 120, B P was 104/80, and the electrocardiogram showe change Recovery was uneventful Four weeks operation the heart sounds had improved in tone, was no gallop rhythm or pulsus alternans, and B P had recovered to 150/90 The electrocardio showed progressive changes towards preponderan the left ventricle She is now up for several daily and free of symptoms Fig 15 shows the h incision

CASE 5 —A missionary's widow, aged 65, who ha a strenuous life for many years in high altitudes A pectoris for twelve years Attacks had become frequent and more severe, and she had been almost fined to bed for over 18 months, being now unable to wash herself A sister has angina She was ref to the clinic by Dr L Lyne of Hove and was adm on Oct 1st Examination very obese, heart enl to anterior axillary line soft aortic systolic mu and very short diastolic whiff, radiogram confi cardiac enlargement, B P 247/117, no œdema, ele cardiogram showed complete bundle branch block large amplitude of Q R S complexes in leads I and

After ten days' treatment with general massage st free diet, and administration cardio-omentopexy was performed at Lambeth Hospital on Oct. 16th 1936 with the assistance of Dr Mansell and Dr Berry under general anæsthesia by Dr Hasler Aleuronat was injected into the pericardial sac and at the site of graft At the end of operation the pulse rate was 69 the B.P 170/90 and the electrocardiogram showed no change Recovery was interrupted by a paroxysm of auricular fibrillation, which began 30 hours after operation and ceased spontaneously 0½ hours later There were two anginal attacks during the first fortnight and none subsequently General massage was begun after five weeks and she was allowed to wash herself In six weeks the blood pressure had returned to 240/112 and was causing symptoms She is now getting up daily for 1–2 hours and has kept free of angina. On a balanced diet the blood pressure has fallen to 210/120 Physical signs of pulmonary collapse have been present at the left base since operation. The electrocardiogram shows no change

CASE 6 (Mr George Mason)—A man aged 63 had suffered from angina for some years He was finally reduced to a state in which walking the length of the ward brought on a severe attack. He was investigated and referred for operation by Dr W G A. Swan On Nov 4th 1936 cardio-omentopexy was performed at the Newcastle General Hospital by Mr Mason with my assistance under general anæsthesia by Dr Philip Ayre There was no post-operative shock and recovery was uneventful

POST OPERATIVE COURSE

In no case has there been any immediate anxiety either during the operation or in the post operative period.

It was clearly essential before contemplating a major operation on the type of patient who suffers from cardiac ischæmia that it should be conducted without disturbance of the normal physiology of the chest and also that shock should be eliminated The first essential was secured by the use of oxygen under positive pressure so that transpleural exploration of the heart could be accomplished without disturbance The elimination of surgical shock was attained in the first place by skilful anæsthesia and secondly by the application of some work on traumatic shock by Slome and myself (1935) in the laboratories of the Royal College of Surgeons We showed that only *two factors were concerned in the ætiology* of shock—namely fluid loss at the time of trauma and nervous impulses generated in the traumatised area and transmitted for some considerable period after the trauma had been inflicted In the operation of cardio-omentopexy an approach is used which permits of an almost bloodless exposure of the heart No large vessels are divided and immediate hæmostasis of any smaller vessels encountered is easily possible—and of greater importance is the fact that the phrenic nerve the main sensory nerve of the region can be immediately blocked so that nociceptive impulses cannot ascend it either during the operation or in the days following

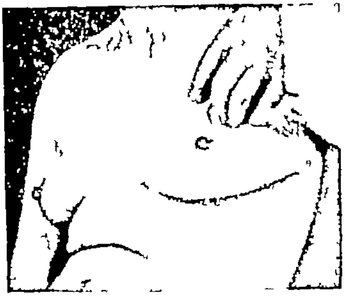

FIG 15 (Case 4)—The incision

THE IMMEDIATE RESULTS

It is the purpose of this lecture to demonstrate that cardio omentopexy is a feasible operation attended with a low immediate mortality A subsequent and detailed report will be published by the medical staff of the Lambeth Cardiovascular Clinic on the after history of the patients submitted to it According to our experimental evidence although vascular connexions are present and demonstrable in three weeks vascularisation increases with time and does not attain its greatest development for at least a year

Our immediate results may be summarised as follows Patient No 1 died of a hæmorrhage from a chronic duodenal ulcer a week after operation No 2 has left hospital in apparently good order No 3 has now a normal pulse can sleep lying down and has a normal degree of activity No 4 had a period of relief from his angina of effort but died of uræmia three months after his operation. No 5 has already gained a degree of activity forbidden her previously by her anginal seizures No 6 has left hospital in excellent condition and his progress will be reported by Mr Mason

Post-operative complications have not been observed in our present series. A temporary paresis of the diaphragm is naturally associated with some degree *of collapse of the lower lobe of the left lung but this* does not seem to be of any great significance and indeed most of our patients have shown signs of renewed diaphragmatic activity three months from the operation full activity should not be longer delayed than six months There has been no case of diaphragmatic hernia the omentum is of course the natural agent for the repair of wounds in the diaphragm—an excellent specimen No 1160 (war collection) in the museum of the Royal College of Surgeons, illustrates this point—and though I have transplanted omentum into the chest of at least 160 animals in the past six years a diaphragmatic hernia has developed in only one of these.

Before concluding this lecture I should like to discuss the alternative operation devised by Beck in which a pedicled graft of the pectoralis major muscle is sutured to the heart Beck has the distinction of being the first surgeon to attempt the direct relief of cardiac ischæmia and with considerable success—in one of his early cases the patient resumed work as a gardener His operation according to the latest figures (August 1936) has six survivors There have been five immediate deaths all in cases with very advanced coronary sclerosis; one from thrombosis of the abdominal aorta one from thrombosis of the middle cerebral artery one from mediastinitis one from a coronary attack and one presumably from heart failure Beck suggests that the comparatively high incidence of post operative thrombosis may be related to the extensive dissection of the pectoral muscle necessary in the preliminary stages of his operation. From my experience of the Brauer operation for mediastino-pericarditis which requires a similar exposure I do not feel that the factors producing post-operative shock can be so well controlled in Beck's operation as in cardio-omentopexy In my hands at least it would be a more serious operation and for this reason, apart altogether from the obvious advantages of the omentum over muscle as a vascularising agent, we have not used it in the Lambeth clinic

Summary and Conclusion

The pathology of cardiac ischæmia has been reviewed, the natural processes of repair have been described, and some account has been given of experimental methods of initiating and supplementing these processes In the Lambeth Cardiovascular Clinic we have established that cardio omentopexy can be performed without immediate disturbance even in a type of patient ill suited to most surgical procedures , our patients have included a man aged 72 and a bedridden woman of 65 There has been no post operative shock and the only immediate death (7 days after operation) was due to a cause unrelated to the cardiovascular system The graft fulfils the immediate function of supplementing the blood-supply to that portion of the myocardium still capable of activity, it prevents further necrosis of any area so ischæmic as to have lost its active function, and it should in some measure act as an insurance against any further obliteration of the coronary tree

I have many acknowledgments to make to the Medical Research Council, who have enabled me to do this work , to the council of the Royal College of Surgeons, who have provided facilities both at Downe and in London , to Sir Arthur Keith and Dr John Beattie, under whose direction the experimental work has been conducted , and to Mr F Watson, senior technical assistant at the Buckston Browne Farm, for his invaluable assistance and advice

I also owe acknowledgment in this as in all my work to Prof Ferdinand Sauerbruch, whose disciple I have been since 1931

I am indebted to Sir Frederick Menzies, medical officer of health of the London County Council, and to the medical superintendents and pathologists of Lewisham Hospital and St James's Hospital for the clinical and pathological facilities afforded me since 1932 The Lambeth Cardiovascular Clinic owes special acknowledgment to Dr P J Watkin, medical superintendent of Lambeth Hospital, and Mr G F Stebbing, surgical consultant, for the ready solution of many administrative and clinical problems and I am personally most grateful to Lord Dawson for his introduction to this lecture and for his stimulating criticism and advice from the earliest stages of the work

IS *p*-AMINOBENZENESULPHONAMIDE THE ACTIVE AGENT IN PRONTOSIL THERAPY?

BY A. T FULLER, Ph D Lond , F I C

BIOCHEMIST, BERNHARD BARON MEMORIAL RESEARCH LABORATORIES QUEEN CHARLOTTE S HOSPITAL, LONDON

BOTH Prontosil and *p* aminobenzenesulphonamide (sulphanilamide) have a protective action against infection by hæmolytic streptococci Colebrook, Buttle, and O'Meara (1936) have shown that whereas sulphanilamide has a directly inhibitory action on the bacteria in vitro, prontosil has no such action The hypothesis has been advanced by Tréfouel and others (1935) that prontosil itself has no antibacterial action but is effective only when reduced to sulphanilamide in the body The following work is an attempt to discover whether sufficient sulphanilamide is produced in prontosil treated animals to account for the protective action obtained

Sisley and Porcher (1911) have shown that while azo dyes, for example chrysoidine, given by mouth are reduced to the corresponding amines, azo dyes administered subcutaneously are not so reduced. Kellner (1936) found that in the rabbit only 22 per cent of injected prontosil was recovered from the urine The urine contained no sulphanilamide, but it reduced Fehling's solution, from which he inferred the presence of the partially reduced hydrazo compound When prontosil was given by mouth to dogs, rabbits, and humans, the urine after diazotising and coupling with β naphthol showed an increased red colour, taken by Kellner to indicate the presence of sulphanilamide This evidence is not very satisfactory, for the prontosil Kellner used itself shows an increased colour when diazotised and coupled with β naphthol

Prontosil is active when given by injection or by mouth It is therefore necessary to show the production of sulphanilamide from both injected and orally administered prontosil. In the following work, prontosil and sulphanilamide estimations have been made on the urine of patients receiving prontosil by mouth and by injection, and on the urine of both normal and infected mice after prontosil injection. Sulphanilamide has been found in significant amount in all cases, and in addition has been isolated from the urine of a prontosil treated patient

The two varieties of prontosil used by Colebrook and Kenny (1936) were used in the following experiments Although both have a curative action there are differences between them which it is necessary to explain

One variety, " Prontosil," is 4 sulphamido 2 4-diaminoazobenzene hydrochloride It is sparingly soluble, dissolving in 1600 parts of slightly acid water and in 20,000 parts of slightly alkaline water It is therefore excreted very slowly a large dose still colouring the urine weeks after administering It has a stronger colour in acid than in alkaline solution and may be diazotised and coupled to give a more intensely coloured dye When it is reduced it gives sulphanilamide and tri amino benzene This latter compound is unstable and is almost certainly destroyed in the body

The other variety Soluble Prontosil the sodium salt of 4 sulphamido phenyl 2 azo 7 acetylamino 1 hydroxy naphthalene 3 6-disulphonic acid, is soluble up to 4 per cent in water It is rapidly excreted practically all in the first few hours after a dose It gives a much deeper colour in alkaline solution than in acid solution and cannot be further diazotised. Reduction of this prontosil yields sulphanilamide together with 2 amino-7-acetylamino 1 hydroxy naphthalene 3 6-disulphonic acid. This does not give the diazo reaction, but does so after acid hydrolysis

METHODS OF ESTIMATION

Either variety of prontosil may be estimated by comparing the colour of the urine with that of a solution of the corresponding prontosil of known strength and the same pH Soluble prontosil can be estimated in the presence of prontosil in strongly alkaline solution when the colour of the second is negligible compared with that of the first but no method has been found of estimating the second when the first is present Sulphanilamide estimations were made by first removing the prontosil by boiling the strongly acidified urine with charcoal cooling to 0 C adding excess of sodium nitrite solution and after a few minutes adding alkaline β naphthol and caustic soda. The red solution thus obtained was then compared in the colorimeter with that obtained in the same way from a solution of sulphanilamide of known strength This reaction the diazo reaction is given by sulphanilamide by reason of its amino group attached to the benzene ring and is not specific for that compound, but normal urines and blood filtrates do not give the reaction

Soluble prontosil was reduced both by stannous chloride and by sodium hydrosulphite and the amino acetylamino naphthol-disulphonic acid separated by acidifying and saturating with salt This compound did not give the diazo reaction being decomposed by the nitrous acid [1]

Sulphanilamide is excreted partly in a conjugated form and the total sulphanilamide was obtained by boiling the decolorised urine in N hydrochloric acid for 15 minutes before diazotising The sulphonic acid produced by the reduction of the soluble prontosil is also hydrolysed by the acid and then gives the diazo reaction

Sulphanilamide may be estimated in blood by the following method

One c cm of blood is laked with 2 c cm of water 1 c cm of 20 per cent trichloracetic acid added and the blood filtered at the pump The filtrate is cooled in ice and one drop of 0·5 per cent sodium nitrite added Equal volumes of standard solutions of sulphanilamide in acid are treated similarly After a few minutes one drop of 1 per cent alkaline thymol and 0·2 c.cm. of 40 per cent caustic soda are added to all tubes and the blood filtrate is compared in the colorimeter against the appropriate standard

This method has been found to give a fairly accurate determination of sulphanilamide added to normal blood down to a concentration of 1 mg per 100 c cm

PRONTOSIL AND SULPHANILAMIDE IN THE URINE AND BLOOD AFTER ORAL PRONTOSIL

Determinations were made on many samples of urine from patients who had received prontosil by mouth and soluble prontosil by injection A few are given in Table I below Corrections have been made for the presence of two kinds of prontosil, and of interfering substances after hydrolysis Sulphanilamide is produced from 1 0 times its weight of prontosil and 3 3 times its weight of soluble prontosil and so in the last column the figures have been multiplied by 2 6 to give the approximate prontosil equivalent of the sulphanilamide excreted.

TABLE I

Patient	Date	Prontosil in urine (%)	Sulphanilamide in urine (%)	Prontosil equivalent of sulphanilamide (%)
Mrs. B	Aug 10th	0 15	0 15	0 39
	" 11th	0·05	0 15	0 39
Mrs. S	10th	0·05	0 12	0 31
	12th	0 13	0 14	0·36
Mrs D	12th	0 15	0·08	0·21

These figures show that up to 75 per cent of the excreted prontosil was in the reduced form

The total three days urine of Mrs G was assayed at frequent intervals during which time she received 4 8 g of prontosil by mouth and 3 g of soluble prontosil by injection A total of 0 8 g of soluble prontosil was found in the urine If we assume that an equal amount of prontosil was excreted (certainly an over-estimate owing to the much slower excretion of this substance) a total of 1 6 g of prontosil is obtained The free sulphanilamide was 0 30 g and the combined was 0 47 g If we assume that half this combined sulphanilamide was really another substance we get a total sulphanilamide of 0 6 g If this is multiplied by 2 6 a prontosil equivalent of 1 6 g is obtained In other words at least half the excreted prontosil was in the reduced form

Sulphanilamide does not appear in the urine until 4–6 hours after the first dose of prontosil

Isolation of sulphanilamide from patient's urine—The final proof of the presence of sulphanilamide was obtained by isolating the substance from the urine in the following way

The urine was acidified and decolorised and the sulphanilamide precipitated as a mercury salt which was removed and decomposed with hydrogen sulphide The mercury free solution was evaporated to dryness, and the sulphanilamide separated from other substances by repeated extractions with acetone It was finally purified by crystallising three times from water It then melted at 162–3 C A sample of sulphanilamide and a mixture of this with the recovered substance also melted at 162–3 C. showing that the two substances were identical The acetyl compounds from both melted at 214–5 C

TABLE II

Day of treatment	Sulphanilamide in blood (mg per 100 c cm)
1st	0 93
2nd	2 [illegible]
3rd	3 7

Sulphanilamide in the blood of a prontosil treated patient—Sulphanilamide was found in the blood of the one patient tested The concentrations are given in Table II, and are of the same order as those in the blood of sulphanilamide treated patients (1 0 to 4 0 mg per 100 c cm)

---

[1] Other amino naphthol-sulphonic acids were prepared and some of them failed to give the diazo reaction, particularly those in which the amino and hydroxyl groups were in adjacent positions in the ring as in the compound under consideration

Excretion of orally administered sulphanilamide —Table III gives the amounts of free and total sulphanilamide in the urine of patients receiving this drug by mouth, and is included to show that humans excrete about half the total in a conjugated form (average figure, 55 per cent)

TABLE III

Patient	Date.	Sulphanilamide in urine (per cent)

EXCRETION OF PRONTOSIL AND SULPHANILAMIDE BY MICE

The mice were kept in groups of ten in a metabolism cage, and the urine was collected in a tube cooled in ice contained in a vacuum flask The urines were removed at intervals for analysis The prontosil and sulphanilamide were estimated as previously described The infected groups were given 0 00003 c cm of a virulent culture of Group A hæmolytic streptococci, Richards, intraperitoneally, and received their first dose of drug subcutaneously two hours later The normal mice received one dose of drug per day, and the infected groups two injections on the first day and one on succeeding days Controls were given the same dose of streptococci but no drug

The experiments were usually allowed to continue for two days The mice were then transferred to their boxes, and the survival of the infected mice noted

(*a*) *Excretion of sulphanilamide* —A preliminary experiment was done on the excretion of subcutaneously administered sulphanilamide by mice Table IV gives the results obtained with normal and infected animals Details have been left out of the Table, which gives the total amounts received and excreted per mouse during the 48 hours of the experiment, the rates of excretion of the sulphanilamide are discussed in a later section

TABLE IV

Mice	Sulphanilamide injected (mg)	Sulphanilamide excreted		Per cent of injected
		Free (mg)	Total (mg)	
Normal	15	6 1	9 6	65
„	7 5	2 9	4 9	65
Infected	22 5	6 1	10 3	46

It will be seen that two thirds of the sulphanilamide injected was recovered from the normal mice and half from the infected mice In both cases 61 per cent of the sulphanilamide was excreted in the free state The concentrations of free sulphanilamide in the urine varied from 0 13 per cent to 0 40 per cent

(*b*) *Excretion of soluble prontosil* —Table V shows the total amount of prontosil injected, and the average quantity of soluble prontosil and sulphanilamide excreted per mouse during 48 hours

TABLE V

Mice.	Soluble prontosil		Sulphanilamide excreted	
	Injected (mg)	Excreted (mg)	Free.	Total*
Normal— Group 1	25	9 4		
„ 2	30	10 8	1 15	2 56
„ 3	15	6 1	1 12	1 44
Total	70	26 3	2 27	4·00
Infected— Group 1	22 5	2 0	1 17	1 51
„ 2	30	8 4	1 03	3 19
„ 3	22 5	3 9	0 87	1 14
Total	75	14 3	3 07	5·84

Unfortunately the total sulphanilamide cannot be found accurately for the figures include a fraction due to another substance liberated by the acid hydrolysis

If it is assumed that as in the sulphanilamide experiment 61 per cent of the total sulphanilamide is excreted free, the corrected total excretion in the normal and infected groups would be 3 7 and 5·0 mg. respectively However, a larger correction is made, on the assumption that half the combined sulphanilamide is due to interfering substances This reduces the total sulphanilamide to 3 1 and 4 4 mg respectively These figures have now to be multiplied by 3 3 to give the amount of soluble prontosil excreted in the reduced form To obtain the quantity of prontosil reduced to secure this excretion, a further correction must be applied to allow for the fact that only 65 per cent and 46 per cent of administered sulphanilamide was recovered from normal and infected mice respectively, under the same conditions. Table VI gives the results expressed as percentages of the prontosil administered

TABLE VI

Mice	Soluble prontosil excreted		Soluble prontosil.	
	Unchanged (%)	In reduced form (%)	Unaccounted for (%)	Reduced (%).
Normal	37 5	13 5	49	2°
Infected	19 1	19 6	61 3	42

Thus, while the normal groups excreted nearly three times as much unchanged as reduced prontosil, the infected groups excreted approximately equal amounts of each In the latter case, 42 per cent of the injected soluble prontosil must have been reduced to obtain this excretion

The prontosil was eliminated rapidly from the normal mice, the urine containing up to 1 2 per cent in the first 4 hours, and only a trace 8–24 hours after a dose The excretion was slower in infected animals, the urine containing only 0 1 to 0 2 per cent during the first 4 hours, but later increasing in concentration Only traces of sulphanilamide were excreted during the first 4 hours the greatest quantity appearing 8–24 hours after the dose, when the excretion of prontosil had almost ceased

(*c*) *Excretion of prontosil* —One group of mice had three doses of prontosil totalling 22 5 mg suspended in gum saline during the first two days Urine was collected for 5 days and the results are given in Table VII

TABLE VII

Day	Prontosil excreted (mg)	Sulphanilamide excreted (mg)
1st	0·40	0·0 2
2nd	0·44	0·070
3rd	0·20	0·050
4th	0·16	0·035
5th	0·11	0·043
Total	1·30	0·270

In Table VIII the above sulphanilamide figures have been converted to prontosil, and expressed as percentages of the prontosil given Again it is assumed that the sulphanilamide excreted is only 65 per cent of the amount actually produced

TABLE VIII

Prontosil excreted		Prontosil reduced (%)	Prontosil not accounted for (%)
Unchanged (%)	In reduced form (%)		
5·8	3·3	3·5	90·7

It should be noted that no combined sulphanilamide was found in this experiment In fact a decreased sulphanilamide reaction was obtained after heating with acid This is due to decomposition which owing to the very dilute solutions concerned (1 in 13 000 to 1 in 35 000) more than balanced the increase due to hydrolysis

These figures show the great difference in behaviour between the two prontosils A moderate dose of soluble prontosil is practically completely excreted in 6 hours Only a small fraction of the same dose of prontosil is excreted in 5 days It is interesting to note that the ratio of prontosil to sulphanilamide excreted by normal mice is about the same for both prontosils although the insoluble prontosil is retained in the body for a much longer time This may mean that the reduction is not caused by simple contact with the tissues

In this connexion it was noticed that the stomach contents of a mouse killed 1½ hours after the injection of soluble prontosil were deeply stained red while the rest of the body seemed free from dye A mouse killed 3 hours after injection had a normal stomach, but the contents of the small intestine were stained red It is possible that the prontosil is reduced in this way in the intestine after absorption into the stomach This would account for the delay in its excretion in prontosil treated animals and agrees with the work of Sisley and Porcher (1911)

DISCUSSION

In normal animals 35 per cent of injected sulphanilamide and 49 per cent of soluble prontosil are not accounted for This is due partly to slight losses during collection and a more complete recovery would have resulted if the urine had been collected for a longer period Only small amounts were found in the body and fæces A part of these drugs is undoubtedly destroyed in the body In the case of insoluble prontosil, 90 per cent was not recovered but a large part of this was left behind in the body staining the tissues an orange colour and excretion was still taking place at the conclusion of the experiment

In infected animals the discrepancies were greater Fifty four per cent of injected sulphanilamide and 61 per cent of soluble prontosil was not accounted for This may be due to retention by the inflamed tissues, or to impairment of kidney function

The infected groups receiving prontosil excreted more sulphanilamide than did the normal groups The question is whether enough sulphanilamide was produced to account for the therapeutic action of prontosil.

In the soluble prontosil experiment equivalent amounts of prontosil and sulphanilamide were excreted and evidence suggests that half the injected prontosil was reduced. Where oral prontosil was also given to patients a still larger proportion was converted to sulphanilamide Allowing for the threefold difference in molecular weights if sulphanilamide is the active agent in prontosil therapy it should be six times as efficient weight for weight as soluble prontosil. This ratio will be affected if there is any great difference in the rates of elimination of sulphanilamide from sulphanilamide treated and prontosil-treated animals

The rates at which normal mice excrete sulphanilamide given by injection and derived from prontosil are given in Table IX

TABLE IX

Drug given	Amount injected in 4 hours (mg)	Per cent. of 24 hour excretion passed in—	
		0–4 hours	0–8 hours
Sulphanilamide	7 5	43	68
"	3 75	44	74
Soluble prontosil	(1·0) (produced)	3	13

It will be seen that the smaller the injected dose the more rapidly is the sulphanilamide excreted and probably the 1 mg produced in the prontosil experiment would be still more quickly eliminated than the 3 75 mg dose if it had been injected Without making allowance for this three quarters of the 24 hourly excretion of injected sulphanilamide has been passed in 8 hours compared with only one eighth of that derived from prontosil If the body can make more use of the steady supply of sulphanilamide from prontosil than of the sudden flood of injected drug this would make prontosil relatively more effective Further discussion is useless without knowledge of the relative efficiencies of the prontosils and sulphanilamide in curing hæmolytic streptococcal disease and this is a problem involving large-scale work both with animals and patients

In the three groups of ten infected mice (see Table V) receiving an average of 25 mg of soluble prontosil each, 7, 7, and 5 had died by the fifth day Six of the ten mice receiving 22 5 mg of sulphanilamide had died by the fifth day The experiments thus fail to show any great difference between the two drugs, but for adequate protection of the animals many more than the three injections received would have been necessary The four-control mice had died by the second day

If prontosil has more protective power than is accounted for by the sulphanilamide produced from it, this further action must be other than a simple bactericidal one, for prontosil itself has little or no streptococcus killing power

SUMMARY

A considerable amount of sulphanilamide is excreted when prontosil is given by mouth or by injection, and it is possible that the therapeutic action of prontosil is due to the sulphanilamide derived from it by reduction in the body

I wish to thank Dr L Colebrook, director, Bernhard Baron research laboratories for his very real help, and Mr W R Maxted for technical assistance

MIXED MENINGOCOCCAL AND STREPTOCOCCAL MENINGITIS

BY A A CUNNINGHAM, M.D Dub, M R C.P Lond, D P H
SENIOR MEDICAL OFFICER, PARK HOSPITAL, LONDON COUNTY COUNCIL

CASES of meningococcal meningitis (cerebro spinal fever) with superadded infection by one or more other organisms have been reported from time to time Extremely rarely the meningococcus is associated with the colon bacillus, *Bacillus pyocyaneus* or Pfeiffer's bacillus More often, though still very rarely, the hæmolytic streptococcus is the offending organism The pneumococcus and the tubercle bacillus are more commonly to be found with the meningococcus and about 50 reported cases belonging to each group were collected by Chalier and Guichard in 1931 Doubtless many others have been noted but not published.

Nothing seems to have been written in this country about the association of meningococci and hæmolytic streptococci in meningitis The streptococci may be secondary invaders in a case of cerebro spinal fever or the two organisms may be associated from the beginning, being found in the first specimen of fluid removed by lumbar puncture In most of the cases recorded the hæmolytic streptococcus has been regarded as the secondary invader

Tessier and Reilly (1920) give an interesting account of streptococcal infection of the meninges—attributed to erysipelas of the face complicating herpes of the lips—which developed about the eighth day of an attack of cerebro spinal fever, which had hitherto responded well to serum therapy The spinal fluid, which was almost clear, became turbid, and hæmolytic streptococci were isolated before death

Collignon and Maisonnet (1910) reported a case in which meningococci were seen on direct microscopical examination of the deposit from the cerebro spinal fluid, but a pure growth of short-chain streptococci was obtained on culture The meningococci were never grown, but the precipitin reaction was positive Although the patient gave a history of otorrhœa there was no evidence of acute or chronic otitis media, no infection of the mastoid was found at operation or post mortem, and in the absence of a definite focus it was presumed that the secondary infection originated in the nasopharynx, the patient having recently had several attacks of quinsy

In Barbier and Lebée's case (1922) death was caused by streptococcal meningitis, the organism being isolated about six days after the onset of the primary meningococcal infection Here again the nasopharynx was regarded as the portal of entry of the streptococcus as also in the case published by Jame, Jude, and Sohier (1932) The latter cultivated meningococcus Type B from the cerebrospinal fluid at the onset of the illness, but four days later, when repeated cultures from the fluid had shown no organisms, a recrudescence of symptoms of meningeal involvement led to further investigation Lumbar puncture produced turbid fluid under pressure and a hæmolytic streptococcus was isolated in pure culture, a hæmolytic streptococcus was also grown from the blood

Morquio (1928) found non hæmolytic streptococci in the cerebro spinal fluid of an infant towards the end of an attack of posterior basal meningitis

If there is no definite suppurative focus of secondary infection it may be hard to prove that the cerebrospinal fluid has not been contaminated from outside —during injection of serum for example This may often have been a reason against the publication of cases of mixed infection

CASE REPORT

A boy aged 11 months was admitted to an L C C. general hospital on Jan 13th, 1936, with follicular tonsillitis and left otitis media For four days before admission he had been continually pulling at his left ear as if in pain, and otorrhœa had begun on the 10th The discharge quickly dried up under treatment, and the child left hospital apparently quite fit on the 22nd, but he had to be readmitted on Feb 17th having had attacks of screaming, without obvious cause, during the previous week, and a recurrence of left ear discharge on the 15th There was active otitis media with profuse otorrhœa but no demonstrable mastoid swelling or tenderness

He remained afebrile till Feb 21st when the morning temperature rose suddenly to 101 4° F and he vomited. The physical signs however, remained unchanged—the temperature fluctuating between 100° and 102° F, with a pulse rate of 150–170 per minute—until Feb 23rd when the aural discharge suddenly ceased and definite stiffness and rigidity of the neck muscles were noted. Lumbar puncture revealed a turbid fluid under pressure and Schwartze's operation was performed on the left mastoid. The mastoid cells were found to be diseased and there was a considerable amount of pus in the left antrum The dura mater bulged on exposure and there was a gush of cerebro spinal fluid when it was incised. but no frank pus was located The child passed a fairly comfortable night and next morning (Feb 24th) the mastoid wound was satisfactory, but the neck muscles were stiffer and the left external rectus of the eye was a little weak. The bacteriological report on the cerebrospinal fluid of Feb 23rd was as follows "Turbid fluid with threads of pus and numerous polymorphs, chlorides 680 mg per 100 c cm globulin greatly increased in amount, a stained film showed numerous Gram negative diplococci plus a few Gram positive cocci, culture on blood agar gave a good growth of meningococci" The pus removed from the left mastoid wound showed hæmolytic streptococci On repeated lumbar puncture 20 c cm. of milky greenish fluid was withdrawn and replaced by 10 c cm of antimeningococcal serum The same amount of serum was given intramuscularly

The child was transferred to the Park Hospital (L C C.) on Feb 25th with a diagnosis of cerebro spinal meningitis. He was pale, poorly nourished, and obviously very ill (temp 100° F, pulse rate 150), though conscious he was extremely irritable and resented examination. There was definite head retraction and Kernig's sign was positive The pupils were circular central, and reacted to light The optic discs were clear and there was no obvious involvement of the cranial nerves. The knee jerks and ankle-jerks were present and equal on both sides but the abdominal reflexes were not elicited and the plantar responses were indefinite Nothing abnormal was found in heart, lungs, or abdomen. A slight purulent discharge was coming from the left mastoid wound, with left otorrhœa but the right ear and mastoid area seemed normal Lumbar puncture gave 25 c cm of very thick turbid C S.F under pressure Meningococcus antitoxin (P D and Co) was injected, 10 c.cm intrathecally and 80 c.cm intravenously Later in the day lumbar puncture was repeated and 30 c.cm. of very turbid fluid was removed and replaced by 15 c cm of serum The fluid showed 56 000 cells per c.mm protein 200 mg per 100 c cm chlorides 670 mg per 100 c cm pus cells and Gram negative diplococci; culture gave a good growth of meningococci Type 2 (Maegraith)

On Feb 26th the general condition was very poor and the neck rigidity and head retraction were if anything worse On cistern puncture 15 c cm of thick gelatinous fluid was removed with great difficulty and a lumbar puncture at the same time gave very similar fluid An attempt was made to irrigate the spinal subarachnoid space with warm isotonic saline solution but continuity could not be established. A further 10 c.cm of serum was given intracisternally and 40 c cm intravenously In the afternoon the right ventricle was explored and 20 c.cm of slightly blood-stained fluid was withdrawn and replaced by 12 c.cm of meningococcus antitoxin As the child's condition became very poor saline irrigation was not carried out The fluid from the right ventricle gave a pure growth of hæmolytic streptococci and the fluid from the cistern grew meningococci This anomalous report led to a closer scrutiny of the blood plates inoculated *from the previous specimens of cerebro-spinal* fluid and colonies of hæmolytic streptococci were found even on the plate inoculated from the first specimen of cerebro spinal fluid obtained on admission The diagnosis of "mixed meningitis now presented itself for the first time and changed the whole complexion of the case

On Feb 27th only 5 c.cm of thick pus could be obtained on cistern puncture but 30 c.cm of very turbid fluid was removed from the left ventricle Since the inefficacy of antistreptococcal serum therapy in streptococcal meningitis is well recognised, meningococcus antitoxin only in a dose of 12 c cm was injected. Irrigation was considered impracticable owing to the extremely poor condition of the child Both cistern and ventricle fluid showed streptococci on direct microscopical examination and hæmolytic streptococci plus meningococci on culture The hæmolytic streptococci now seemed to have gained the ascendancy for the colonies, which at the beginning of the illness were difficult to locate amid the more abundant meningococcal growth now definitely outnumbered the meningococcal colonies Next morning (Feb 28th) the child was comatose; opisthotonos was accompanied by almost continuous convulsive movements of the limbs which were first noticed during the previous night, and which ended in death

Samples of fluid were obtained by ventricle cistern and lumbar puncture and hæmolytic streptococci were found in all three specimens with a less abundant growth of meningococci in the ventricle and cistern fluids only The pus from the left mastoid wound gave a 90 per cent growth of hæmolytic streptococci serologically identical with those isolated from the cerebro spinal fluid which belonged to a rather uncommon group (Type 1.) No growth was obtained from the blood after 48 hours incubation

Post mortem findings will in skull—Much congestion of the vessels of the dura with loss of continuity and evidence of trauma beside the left mastoid. Greenish yellow exudate over the entire surfaces of the cerebral hemispheres and cerebellum, particularly abundant at the base of the brain covering the pons and filling the interpeduncular fossa also opaque areas of purulent exudate scattered over the surface of the temporal lobe on each side Subarachnoid hæmorrhages on the left side of the cerebellum anteriorly the left Rolandic area and the apex of the left occipital lobe Left lateral sinus unaffected Pus in the right middle ear with evidence of spread of infection to the mastoid cells which were broken down and necrotic though the overlying bone was not eroded.

DISCUSSION

The mere presence of an organism in a specimen of cerebro-spinal fluid is not evidence of meningitis the infection has to be proved by repeated bacteriological examination of specimens removed with rigid aseptic precautions This was done in the present case Owing to the preponderance of meningococci in the early specimens the meningococcus can be regarded as the primary invading organism The left mastoid was undoubtedly the source of streptococcal infection, for the hæmolytic streptococcus isolated therefrom was serologically identical with that later obtained from the cerebro-spinal fluid A hæmolytic streptococcus was also isolated post mortem from the right mastoid, but we have no evidence that this contributed to the meningeal infection.

The time of onset of the secondary infection is difficult to determine The presence of acute mastoiditis complicated by purulent meningitis was held to justify immediate operation even before complete bacteriological investigation of the cerebro spinal fluid could be carried out At operation the dura mater was incised in the search for a possible intracranial collection of pus. This incision may have been the path of secondary infection but it is quite likely that the streptococci reached the meninges by *direct extension from the ear* since the cerebro spinal fluid removed before operation showed many Gram negative diplococci with Gram positive cocci In the light of events it is unfortunate that the idea *of a mixed infection was not pursued at that early* stage and that the Gram positive cocci were regarded as contaminants.

One lesson of the case is that if acute mastoiditis is accompanied by signs of meningitis a complete bacteriological examination of the cerebro spinal fluid, obtained under rigid aseptic precautions, must be carried out before any operation is attempted If the meningitis proves to be purely meningococcal spinal drainage with intensive serum therapy (intravenous and intrathecal) is indicated Conservative measures will usually suffice for the treatment of the associated acute mastoiditis. If on the other hand there is a mixed meningeal infection the usual anti meningococcal therapy must be combined with immediate operation on the infected mastoid But unless there is clinical evidence of an intracranial abscess the membranes of the brain should not be opened Antistreptococcus serum appears to be of little or no value in these infections

I wish to thank Dr H S Banks medical superintendent of Park Hospital, for permission to publish the case and I am indebted to Dr J L McCartney director of the Southern Group Laboratory for the bacteriological and pathological findings

OVERBREATHING TETANY

CHANGES IN THE CALCIUM OF SERUM, SERUM ULTRAFILTRATES, AND CEREBRO SPINAL FLUID

By R A McCance, M D , Ph D Camb ,
F R C P Lond
ASSISTANT PHYSICIAN IN CHARGE OF BIOCHEMICAL RESEARCH AT KING S COLLEGE HOSPITAL LONDON AND
E Watchorn, Ph D Camb
BIOCHEMICAL LABORATORY CAMBRIDGE

THE chemical changes both in the blood and urine during overbreathing tetany have been extensively investigated, and recently Barnes and Greaves (1936) have extended their investigations in two cases to include the cerebro spinal fluid (C S F) These authors considered on the basis of certain published work that they were justified in "using the C S F calcium as an index of the diffusible calcium of the blood " The authors stated that they found approximately 0 5 mg per 100 c cm less calcium in the C S F of two patients during an attack of overbreathing tetany than at another, normal (but presumably not immediately preceding), time Their conclusions were that the diffusible calcium of the serum was reduced during overbreathing tetany to a still greater extent

The theoretical assumptions of Barnes and Greaves are not in keeping with modern views of the way in which the C S F is formed The published evidence has been extensively reviewed by Flexner (1934), Gilligan, Volk, and Blumgart (1934), Greenfield (1936), Kral, Stary, and Winternitz (1929), and McCance (1936)—see also Gregory and Andersch (1936)—so that it is unnecessary to discuss the matter again It is enough to point out that it is very improbable that the calcium in the C S F is an index of the diffusible calcium of the serum Nevertheless, the experimental findings of these authors appeared to be so important that it was decided to repeat some of their work under rigid experimental conditions For this purpose two subjects were selected a woman, P Q , aged 34, who suffered from severe attacks of hysterical overbreathing tetany , and a normal woman, M S , aged 28

EXPERIMENTAL PROCEDURE

The experiments were carried out at King's College Hospital After emptying the bladder the subjects sat down on a chair with their arms resting on the back A needle was inserted into the thecal space in the lumbar region 5 c cm of fluid was withdrawn and the needle left in situ Blood was also removed from the antecubital vein with very slight constriction or with none at all and allowed to clot under a 1 in layer of paraffin At no time was the blood in contact with the air until the plasma had been separated The subjects next overbreathed voluntarily When tetany was well established, a second vein puncture was made and a further 5 c cm of spinal fluid removed The subjects were then told to stop overbreathing The patient was unable to do so and carbon dioxide had to be administered to remove the tetany which was most severe and extended to opisthotonos A third vein puncture was made and a final 5 c cm of spinal fluid was removed as soon as the tetany had quite disappeared A second specimen of urine was obtained as soon as possible after the third vein puncture On the next day the serum was separated from the clot and both sera and C S F labelled in cipher and taken at once to Cambridge where the ultrafiltration and all chemical determinations were carried out in duplicate by one of us (Greenberg and Gunther 1929, McCance and Watchorn 1931, Watchorn and McCance 1932)

RESULTS

The protocols of the experiments are given below and the analytical results in the Table It will be observed that tetany began to develop after a period of only 2½–3 mins' overbreathing in the normal subject M S , tetany began to develop after 3½ mins in the patient P Q The serum calcium rose during overbreathing and fell again immediately afterwards This rise is in agreement with the results reported by a number of authors The ultrafiltrable calcium also rose during overbreathing The ratio of the ultrafiltrable to the total calcium remained virtually unchanged in the normal subject. The ratio fell slightly in the patient throughout the whole experiment but was always within normal limits The C S F calcium did not fall during over

Subject M S (normal)

Time P M

breathing and did not in fact show any significant change The C S F inorganic phosphorus also showed no significant change during overbreathing

DISCUSSION

These results do not confirm those of Barnes and Greaves. An obvious criticism of their results is the fact that they do not seem to have taken their specimens of normal sera and C S F during the main experiment but at some other time

Our results differ from those of Barnes in showing a rise of total serum calcium during overbreathing—not an important difference since the rise is known to be a variable phenomenon—and in the constancy of the C S F calcium The present results conflict with the theoretical conclusions of Barnes and Greaves in the fact that the C S F calcium was considerably below the ultrafiltrable calcium and in that the latter did not fall during overbreathing (Gunther and Greenberg 1931 Herbert 1933)

If the hypothesis of Barnes and Greaves were accepted it might be argued that since no change was found in the C S F none or only a very small one could be expected in the ultrafiltrate Herbert (1933) however and Gregory and Andersch (1936) have shown very convincingly that the C S F calcium does not represent the diffusible serum calcium and that the differences cannot be explained as due to the slow attainment of equilibrium between the C S F and the serum since the differences may be *maintained for many weeks*

The results here reported also indicate that the ease with which tetany can be induced by overbreathing has little diagnostic significance (see protocols) The time at which tetany develops and its severity depend upon the susceptibility of the subject to the alkalosis so produced Thus tetany may not develop clinically until overbreathing has been in progress for some time but cases have been recorded in women after very slight hyperventilation (Barnes and Greaves 1936 McCance 1932) In most of the experiments reported tetany has only developed after 15–45 mins overbreathing but it should be noted that women have seldom been the subjects. It is our experience however that mild tetany can sometimes be produced by 4–5 mins overbreathing even in normal men and it is possible that in women the time required may often only be 2–4 mins. However that may prove to be the present results make it clear that perfectly normal persons may be as susceptible to alkalosis and tetany as those unfortunate people who are liable to attacks of uncontrollable overbreathing and its alarming sequelæ

SUMMARY

Spontaneous overbreathing in women sufficient to cause severe tetany brought about a rise in the serum calcium a small rise in the ultrafiltrable calcium but no change in the cerebro spinal fluid calcium or phosphorus

Susceptibility to alkalosis tetany varies from one person to another and a high degree of susceptibility is quite compatible with a perfectly normal life The ease therefore with which tetany can be induced has no diagnostic significance

We are very grateful to Dr J C. Winterler and Miss E. M Widdowson for their help We are also indebted to the subjects and particularly to M S for her whole-hearted cooperation in an experiment which necessitated spending a fine week-end in bed.

THE CEREBRO SPINAL FLUID IN SPONTANEOUS OVERBREATHING TETANY *

By J N Cumings M D M R C P Lond
ASSISTANT PATHOLOGIST TO THE NATIONAL HOSPITAL, QUEEN-SQUARE, LONDON AND

E A. Carmichael, M B Edin F R C P Lond
ASSISTANT PHYSICIAN AND DIRECTOR OF THE RESEARCH UNIT AT THE HOSPITAL

Recently Barnes and Greaves (1936) have discussed the rôle of calcium in spontaneous overbreathing tetany and have recorded cases in which there was a fall in the cerebro-spinal fluid (C S F) calcium during tetany They suggest that this fall was associated with an alkalosis with consequent lowering of the diffusible calcium of the blood which lowering was immediately reflected in the C S F calcium content The following report gives our findings on two such cases of overbreathing tetany in which the C S F and blood calcium contents were estimated these findings will be shown to disagree with those of Barnes and Greaves.

THE ESTIMATIONS

The two patients were admitted to the National Hospital on Sept. 5th and 4th 1936

Case 1 —A. B a woman aged 32 had had for seven years attacks characterised by an onset with hyperpnœa followed by drawing up of the fingers and loss of voice They lasted several minutes but in none had she been unconscious On examination no signs of organic disease of the nervous system were found.

Case 2 —C D a woman aged 27 years For two years before admission she had suffered from attacks in which she would gradually become stiff in the hands and feet Occasionally the stiffness would be preceded by a tingling in the fingers and toes In an attack seen in hospital there was at the onset considerable alteration in the rhythm of breathing which became very deep and somewhat hurried. During this attack tetany developed Between the attacks no physical signs of organic alteration of the nervous system could be established

These two patients were put on a diet containing a known amount of calcium and the calcium excretion in the urine and fæces estimated on the days of examination Table I gives the results

Lumbar puncture was performed on both patients C S F was removed and blood taken at the same time the lumbar puncture needle was then left in situ throughout the whole of the experiment Each subject was made to overbreathe and when

tetany was well established, C S F and blood were removed simultaneously Overbreathing was stopped and when the patients had completely recovered further samples of C S F and blood were removed (Table II) It is of note that in one case tetany occurred in 10 minutes and in the other in 16 minutes, both times being earlier than often occurs in normal subjects, although this is by no means the rule

TABLE I

Calcium Metabolism

—	A B		C D	
	Date	Calcium (g per day)	Date	Calcium (g per day)
Intake	Oct 3rd „ 4th	1 28	Oct 10th	1 49
Output	Urine Oct 3rd „ 4th	0 26	Urine Oct 10th	0 31
	Fæces Oct 3rd „ 4th	1 25	Fæces Oct 10th	0 38
Balance		−0 23	—	+0 8

TABLE II

Time Relationships of Overbreathing and Tetany

Sequence of events (C S F and blood taken before experiment)	Time	
	A B Oct 3rd	C D Oct 10th
Lumbar puncture	11 27 A M	3 8 P M
Began overbreathing	11 34½	3 8½
Very slight tetany in hands	—	3 13
Severe tetany	11 44½	3 20
C S F and blood taken during tetany	11 46	3 26
Overbreathing stopped	11 48	3 26½
Patient normal C S F and blood taken	12 1	3 36

The calcium was estimated by Kramer and Tisdall's method (Harrison 1930) the serum having been removed from the blood as soon as was possible All three specimens of C S F and of serum from each patient were put up simultaneously and in duplicate and in no case was a significant difference in the duplicates found (Table III)

TABLE III

Calcium Estimations (mg per 100 c cm)

—	A B		C D	
	Blood	C.S F	Blood	C.S F
Before tetany	9 7	3 9	10 3	4 2
During tetany	9 4	3 8	9 8	4 4
After tetany	9 4	3 8	11·0	4 8

RESULTS

It is seen that in both cases there was a slight but definite reduction in the serum calcium during the stage of tetany Scott and Cantor (1933) found a slight rise, while McCance (1932) found it stationary in one case and very slightly increased in another In A B there was a very slight decrease and in C D a very slight increase of the C S F calcium, but both are within the limits of experimental error

In experimental work upon other substances it has been generally recognised that there is either no rise or only a very slow alteration of the C S F contents on altering those same constituents in the blood (Cumings and Carmichael 1934, Jacobson 1932, Fremont Smith and Dailey 1925)

From such work it seems very unlikely that there could be changes in the C S F calcium such as Barnes and Greaves describe, especially as such changes would have occurred presumably in roughly 5 mins —the time taken for tetany to appear In these experiments of Barnes and Greaves there is no record that the resting specimens were taken immediately before the period of tetany, if they were taken on a previous day they can hardly be described as being necessarily identical with ones that might have been taken at the commencement of the experiment In our two cases we have overcome such criticism by leaving the lumbar puncture needle in situ throughout

For a similar reason it does not seem justifiable to us to consider the necessity that C S F must be formed across the endothelium of small vessels of the spinal meninges as Barnes and Greaves have postulated in explaining this decrease in the C.S.F calcium

SUMMARY

In two cases of spontaneous overbreathing tetany there was no appreciable decrease in the C S F calcium although a small decrease took place in the serum calcium in each

RETROPERITONEAL SARCOMA OF UNUSUAL DISTRIBUTION

BY HARRY WATERS, M.B Dub
AND
DAVID LEVINE, M.R C S Eng
HOUSE PHYSICIANS ROYAL WATERLOO HOSPITAL, LONDON, AND
BERNARD MYERS, C M G , M.D Edin , F R C P Lond
PHYSICIAN TO THE HOSPITAL

With a Note on the Histology by

F A KNOTT, M.D , M.R C P Lond.
PATHOLOGIST TO THE HOSPITAL AND READER IN PATHOLOGY TO THE UNIVERSITY OF LONDON

WE have seen references to 24 cases of retroperitoneal sarcoma, but so far none has been exactly parallel with that described here Judd and Lawson (1933) of the Mayo Clinic state that of 46 surgical cases the ratio of male to female patients was 2 to 1 The disease is most common in the fourth fifth and sixth decades of life. The symptoms resulting from the disease are usually vague and there may be no impairment of health until the lesion has advanced to a late stage Surgical removal of the lesion was permanently successful in 15 cases They state that this form of treatment combined with heavy doses of radium and Röntgen therapy is the treatment of choice In their series the order of frequency was pure sarcoma fibrosarcoma, lymphosarcoma myxosarcoma, liposarcoma, fibromyxoliposarcoma fibromyxosarcoma myosarcoma and paraganglioneuroma.

Funk and Wickstrom (1931) quote a case of a man aged 50 admitted to hospital with pain in the left side of lower part of back and left leg

There was a history of weakness and loss of weight during the last two years A few days before death he showed signs of meningeal irritation with coma and neck rigidity The autopsy showed a reticulum cell sarcoma, which was primary in abdominal lymph nodes with metastases in lung ribs pancreas kidneys and vertebræ

Pow (1936) quotes a case of retroperitoneal sarcoma with pain referred to the thigh in a man aged 25

There was considerable rigidity of right loin but no definite mass was felt Temperature was not raised sleep almost impossible albumin and pus in the urine; moderate leucocytosis After two days unconsciousness patient died. Post mortem the kidneys appeared normal macroscopically but just below the lower pole of the right kidney infiltrating the right iliopsoas muscle was a large fixed sarcomatous mass with many outlying nodules Nerves running down towards Poupart s ligament were involved. No secondaries were seen in the liver but both lung bases presented numerous small growths

Murray Newton (1932) describes a girl aged 17 who had a retroperitoneal sarcoma which apparently disappeared by treatment with radium and deep therapy

Although not frequently met with therefore these cases may occur in any practice and we make no apology for publishing our own experience.

CASE REPORT

A married woman aged 68 was admitted to the Royal Waterloo Hospital on May 10th 1936 at the suggestion of one of us (H. W) on account of abdominal pain, loss of weight anorexia, and anæmia.

She was quite well till some 3 to 4 years ago when she developed abdominal pain which came on ½–1½ hours after food It was relieved by alkalis and eructation The appetite began to fail and her general health from that time gradually became more and more unsatisfactory

A year ago she had an acute attack of abdominal pain central in origin which passed up the left side of chest associated with profuse vomiting which lasted 12 hours. Two similar attacks occurred six months ago, when the character of her indigestion changed, there being pronounced anorexia and the pain becoming constant and unrelieved by alkalis Asthenia and loss of weight quickly followed Four weeks before admission she complained of pain in the spine and lower part of the back with weakness that quite prevented her sitting up in bed. A week later there was a "stroke" with loss of power in the legs slight drooling of saliva from the right side of the mouth, possibly speech defects and loss of rectal sphincter control She gradually improved but there was vomiting again and increased abdominal pain She was usually constipated but there was now occasional diarrhœa Any exercise caused some dyspnœa. The patient has had three children one of whom died in infancy from caries Her husband died from tabes dorsalis

On admission the notes state "patient is a thin cachectic woman a spotty brown pigmentation is present on chest abdomen arms and legs Mucous membranes pale hæmoglobin 40 per cent; tongue dry and red. The pupils reacted to light and accommodation; no cranial nerve defects found. A few râles were present at the right base The circulation was normal and the blood pressure was 130/84 mm Hg

There was some fullness in the abdomen, especially on either flank and a sense of resistance in left hypochondrium and partly also in right There was no indication of fluid. It seemed as if there was a ridge to the right and the left of the stomach which appeared to be connected with it These areas were tender and painful. Per rectum some ballooning of the rectum was apparent but no tumour or glands felt and nothing abnormal was noted per vaginum Legs thin reflexes normal The stools were normal and also the urine

Left septic parotitis developed with a rise in temperature to 101° F Having gone steadily downhill despite treatment with liver extract and iron which produced no effect on the hæmoglobin the patient died suddenly on June 5th

Investigations.—Blood count (May 20th):

Red cells	2,600,000	White cells	9800
Hæmoglobin	40%	Polymorphs	71.5%
Colour-index	0.8	Eosinophils	1.5%
		Hyalines	6%
		Lymphocytes	20%
		Basophils	1%

On June 20th the hæmoglobin was 41 per cent

Radiogram of stomach: No evidence of new growth of the stomach, but there may be something displacing the stomach to the left

Occult blood test gave weak positive result with guaiacum, but negative spectroscopically

Fractional test-meal There was no blood, bile or mucus seen; starch was present throughout; free hydrochloric acid and total acidity were within normal limits

Post mortem report.—The body was thin and cachectic rigor mortis present Left suppurative parotitis Basal congestion of lungs but no consolidation; mild atheroma present in the aorta and blood vessels

The left and right hypochondrial regions were the site of two large tumours retroperitoneal in position. The left was larger than the right, producing a forward displacement of the stomach. The spleen was compressed to ½ normal size but otherwise normal The left tumour together with the kidney to which it was attached, and the pancreas were removed in one mass The right was separated from the under surface of the diaphragm being adherent to it only by fibrous tissue and removed with the kidney The tumours were easily removed, invasion of the surrounding tissues apparently being prevented by their capsules fibrous tissue structures ½ in thick. No evidence of normal suprarenal gland was found on either side in the tumour or suprarenal area

The liver showed fatty degeneration and no macroscopic evidence of secondary deposits. The bladder pelvic viscera, and intestines were normal No enlarged glands were discovered except in the pancreas (V I) The brain was normal; no secondary deposits found

Histological report.—The specimens brought to the laboratory from the post mortem room consisted of two large ovoid tumours of approximately 9 [illegible] × 4 in Except at one mid lateral zone corresponding in each case to that part of the tumour lying nearest to the spine each tumour was encased in a fibrous capsule Both tumours lay completely behind the peritoneum When cut into each was found to consist of a massive neoplasm thrusting aside and quite separate from a compressed but otherwise normal kidney The growth extended around the renal vessels encircled the ureter and was probably continuous with similar growths in the aortic region The tail of the pancreas was in close contact with but separate from the growth on the left side On the right side the liver was not adherent to the tumour Careful search for suprarenal tissue was made in both specimens but none could be found. The central part of the main neoplastic mass was breaking down resulting in a central cavity about 3 in. in diameter containing necrotic structureless material and much old and recent blood-clot In both tumours hæmorrhages probably occurred within 48 hours of death. To the depth of about 2 in tissues of the tumour had not degenerated, and from this level various sections were cut The greater part of the neoplasm consisted of sarcomatous tissue in which the individual cells were round, of medium size, rarely showing a tendency to elongation. They possessed a moderate amount of cytoplasm, and their nuclei stained moderately well (Fig 1) The intracellular tissue showed some tendency to fibrillation and occasionally well formed vessels could be seen, but on the whole the vascular channels were very imperfect and poorly supported, many small hæmorrhages being seen About 5/6 of the whole tumour had the above appearance, but in a few areas the cell type changed and from being chiefly round became very mixed and included numerous multi nucleated giant cells of various sizes In these zones the vessels were rudimentary and the hæmorrhages more numerous (Fig 2)

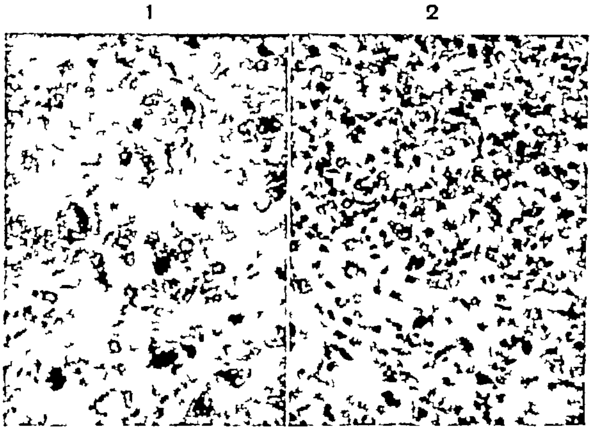

FIG 1 —Structure of greater part of the sarcoma medium-sized round cells

FIG 2.—Structure of areas comprising about ⅙ of the tumour tissue mixed-celled sarcoma with several giant cells.

The bulk of the tumours on both sides would be described as a fairly characteristic round celled sarcoma with local transitions to the mixed cell type The general appearances of the specimens suggest a retroperitoneal origin in the aortic region with extension taking place in all directions but most strikingly along the line of the renal vessels, producing two large tumours in the renal region compressing but not actually involving either kidney It is a case of retroperitoneal sarcoma of somewhat unusual distribution

DISCUSSION

There was no evidence of disease of the stomach or bowel, nor of a primary blood disease, lymphadenoma, renal or splenic tumour, or ovarian, pelvic or rectal There was no reason to suspect hydatids The probability was in favour of a malignant tumour in the abdomen near the left border of the stomach The difficulty, however, was to account for the feeling of fullness and resistance to the left and right of the stomach, which appeared to be placed between two resisting areas, but from investigations was apparently normal itself. Was one tumour present or two? That was difficult to determine during life Her age, wasting, appearance, anæmia, abdominal pain and swelling, together with her history, strongly suggested an abdominal malignant growth. It was hoped to give her the benefit of operation, but her general condition did not merit it Unfortunately the patient was too weak to have a barium enema and her sudden death prevented further clinical investigations

AN INVESTIGATION OF THE RELATIVES OF PATIENTS WITH GASTRIC CANCER

BY A E LEVIN, M D

AND

B A KUCHUR, M D

(*From the Maxim Gorky Medico Genetical Research Institute, Moscow*)

IN studying the rôle of inheritance in the ætiology of gastric cancer we were interested, among other things, in determining a possible connexion between the disease and secretory disturbances

Our series consisted of 167 relatives of patients with gastric cancer—34 sibs, 103 offspring, and 30 of the more distant relatives The stomach contents of these relatives was examined by means of the Boas Ewald test meal, with the following modification 60 grammes of unsalted white bread and 250 c cm of distilled water For a control population we used husbands and wives of gastric cancer and ulcer patients, also persons who at one time were operated on for cancer of the breast, uterus, and skin, and their relatives, as well as some other patients All of these, 150 people in all, were investigated by the above mentioned method

Of the 167 relatives, 23 (13 8 per cent) showed absence of free hydrochloric acid in the stomach contents among the 67 males there were 10 cases (14 9 per cent), among the 100 females there were 13 cases (13 0 per cent) of achlorhydria The higher frequency of achlorhydria among the relatives as compared with the controls is evident from Tables I and II

TABLE I

Incidence of Achlorhydria in the Families of Patients with Gastric Cancer and in a Control Population

—	Male (%)	Female (%)	Over 30 years (%)	Under 30 years (%)	Total (%)
Relatives	14 9 ± 4 6	13·0 ± 3 4	30 8 ± 5 7	2 9 ± 1 7	13 8 ±
Control group	3 2 ± 3 2	8 4 ± 2 5	10 1 ± 2 9	0	3 ± 1

TABLE II

Details of Age groups in Table I

Age	Relatives			Control group		
	Total	Achlor hydria	Per cent	Total	Achlor-hydria	Per cent
0–10	11	—	—	3	—	—
11–20	44	—	—	22	—	—
21–30	47	3	6 4	16	—	—
31–40	40	11	27 5	38	2	5·3
41–50	12	3	25·0	36	2	5·6
51–60	12	6	50·0	27	7	5·9
61–70	1	—	—	7	—	—
71–80	—	—	—	1	—	—
Total	167	23	13 8	150	11	7 3

RESULTS

The presence of a definite familial trend—the high incidence of achlorhydria among the older relatives of patients with gastric cancer—points to some rôle of heredity in the ætiology of this disease No such trend was noted among the persons who had any other localised cancer (uterus breast skin) and their relatives among 45 in this group over 30 only 3 cases (6 7 per cent.) had achlorhydria It seems to us, therefore that achlorhydria in the families of gastric cancer patients is one expression of the hereditary factors determining the particular localisation of the growth. In some of the cases of gastric cancer achlorhydria appears to be a forerunner of the disease

DANGEROUS RECTAL TRAUMA DUE TO A RIGID NOZZLE

By D Denham Pinnock M.B Melb F R C S Eng
SURGEON TO THE NATIONAL TEMPERANCE HOSPITAL, LONDON AND TO THE VICTORIA HOSPITAL FOR CHILDREN LONDON

An article by H H Rayner (*Brit med J* 1932 1 419) attracted my attention at the time but I confess that since no case of this kind had been seen by many colleagues or myself in some 25 years of hospital and private practice I still thought that the risk of serious damage due to a rigid douche nozzle must be very slight I have been called in consultation to two cases in the period of six weeks This has impressed on me the real danger of anything other than a rubber tube being passed into the rectum by a nurse who cannot be expected to have a sound knowledge of the anatomy of the rectum with its curves, and the valves of Houston especially as the mucous membrane of the rectum according to Lockhart-Mummery is only slightly sensitive above 1½ in from the anus

CASE 1 —A lady aged about 55 years though quite well was having a course of colonic lavage as she thought it was a very clean thing to do She was having the third of the course about 4 P.M. one day when she was suddenly seized with violent pain in the lower abdomen and lower back and collapsed. A nurse came to her aid but a minute or so elapsed before the douche was stopped and she was lifted on to a couch where she was given sal volatile and warm bottles applied. She felt very ill and it was 7 P.M before she was taken to her flat in a taxi by one of the nurses and put to bed By 9 P.M she was feeling worse and sent for her doctor who called me in consultation

She was found to be severely shocked and presented the signs of a pelvic peritonitis On rectal examination no tear could be seen or felt but there was a little blood on the examining finger A diagnosis of perforation of the rectum was made and operation advised. She was removed to a nursing home but then refused operation and it was 2.30 A.M before she realised the gravity of her condition and consented.

On opening the abdomen by a median subumbilical incision the pelvic coils of small intestine were found to be injected, and there was about half a pint of thin fluid in the pelvis No perforation of the peritoneum could be seen, but the striking thing was the enormous extraperitoneal œdema in the pelvis and left side obscuring the rectum bladder iliac and descending colon Not less than 2 pints of fluid could have distended the tissues in this way The free fluid was mopped out a tube drain inserted into Douglas s pouch and the peritoneum closed round this The extraperitoneal tissues on the left were then opened and a large amount of fluid escaped, a tube was inserted into this region and the skin and subcutaneous tissue closed round this Lastly a valvular cæcostomy was performed and an intravenous saline given and the patient returned to bed

By the 3rd day she appeared to be progressing well there was almost no drainage so the tubes were removed. On the 5th day her temperature rose to 100 F and a seropurulent discharge began which during the next few days became purulent Her chief complaint was a pain in the lower back, deep to the sacrum The cæcostomy was functioning well For the next 3 weeks there was little change, she had a moderate amount of purulent discharge with an occasional foul-smelling slough coming away In the 4th week some hæmorrhage occurred and she began to lose ground.

A blood transfusion of 300 c.cm was given and improved her condition considerably A few days later 400 c cm blood were transfused and under gas oxygen an incision was made into the left iliac region The extraperitoneal tissues were opened and a drain put in where a track was found extending down into the pelvis Two weeks later as she was not making progress lipiodol was injected through a catheter introduced into the left iliac wound, and a stereoscopic radiogram taken This showed that there was a cavity at the back of the rectum opposite the lower end of the sacrum 2½ by 1½ in in size corresponding to the position where the penetration of the bowel had occurred and where the main damage had been done to the tissues.

Naturally an operation to expose this cavity by removal of the coccyx and lower part of the sacrum was advised but this was refused for some days when after a consultation with Sir Thomas Dunhill the patient agreed and after this made a rapid recovery The cæcostomy took some time to close completely and a tiny sinus discharging a little stained mucus remained for another month but then closed without further trouble She has remained in good health since and from a reading of the reports of similar accidents appears to have been very fortunate

The douche nozzle used in this case was brought to me for inspection and is a truly dangerous weapon consisting of a metal tube some 12 in long as thick as a slate pencil with a ball joint 4 in from the end which had two lateral openings and which was merely rounded not mushroomed I was also informed that the douche can was elevated some 6 ft above the level of the pelvis It is easy to imagine this nozzle impinging on the under side of a valve of Houston and some movement on the part of the patient pressing it through the insensitive mucous membrane and the force of the douche pouring its fluid into the perirectal tissues

CASE 2 —This was a man aged about 58 of the plethoric type who was accustomed to having his bowels act twice daily and one day missing his afternoon motion sent to a nearby nursing home for a nurse to come and give him an enema. This was done with a Higginson syringe with the bone nozzle Apparently he felt pain almost immediately the nurse commenced the administration and only two or three bulb-fulls were injected He had no result from the enema nor did the fluid return but there was a little bleeding thought to be from hæmorrhoids which were present Next day feeling far from well and having passed nothing but some blood, he sent for his doctor who called me in consultation.

On examination the anal region was found to be rather swollen and slightly reddened posteriorly and on the right and was tender A rectal examination disclosed a ring of hæmorrhoids and above this a thickening in the mucous membrane of the right postero lateral wall of the rectum extended as high as the finger could reach The actual perforation of the mucous coat could not be seen or felt but there was some bleeding after my examination A diagnosis of perforation of the mucous membrane with injection of the fluid into the submucous region was diagnosed and operation (cæcostomy) advised, but this was refused by the patient

Some five days later during which time he had suffered much pain, he passed a slough about 7 in. long and 1½ in wide consisting of the necrosed mucous membrane of the posterior wall of the rectum. He now consented to operation and a cæcostomy was performed. For about 5 days he seemed to be making good progress and clean granulations were appearing when he died suddenly from a stroke or possibly a cerebral embolus

Comparing these two cases it is interesting to note that the former though the rectal wall had been penetrated and perirectal and subperitoneal spaces injected with a large amount of non sterile fluid, survived after a long illness, whereas the latter, when the mucous membrane was only stripped up and at most a few ounces of fluid injected, died Both, however, emphasise the great danger of nurses introducing solid nozzles into the rectum, and it should be a definite rule that nothing but a pliable rubber tube should be used for the administration of enemata or for rectal lavage

CARDIOVASCULAR CHANGES FOLLOWING ARTERIOVENOUS ANEURYSM

By G Basil Price, C M G , M D , F R C P Lond

LATE CONSULTING MEDICAL ADVISER TO THE MINISTRY OF PENSIONS AND CONSULTING PHYSICIAN TO MOUNT VERNON HOSPITAL

So long ago as 1875 Nicolodami noted that in cases of arteriovenous aneurysm tachycardia might be present and cardiac hypertrophy take place Wrail in 1877 described the same phenomena Osler pointed out in 1915 that venous stasis was the most serious sequel, sclerosis of arteries with dilatation developing on the proximal side He quoted the case of a patient who had in 1898 an arteriovenous aneurysm in Scarpa's triangle, and died in 1911 having suffered pain and progressive failure of circulation due to cardiac changes For this reason operative measures on the aneurysm were discouraged, the connexion between the arteriovenous aneurysm and cardiac changes as sequelæ not being realised (Wright, 1933)

Lewis and Drury (1923) have pointed out that if the blood leaks from the arterial system through channels other than the natural ones provided by capillaries and at sufficient rate, such leakage will change the blood pressure It seems a matter of indifference whether the leak is back into the ventricle, into the pulmonary artery via a patent ductus arteriosus, or into a vein by direct anastomosis The nearer an arteriovenous aneurysm is to the heart, and the larger the communication, presumably the more serious is the factor leading to cardiac embarrassment and stress Theoretically it seems possible that the negative pressure in the veins close to the heart might become even a positive one, and have pulsation communicated Under these circumstances an immediate embarrassment of the right heart would be likely to ensue, leading to persistent failure of that side with lowered blood pressure, especially the diastolic (Hill and Flack sign) This appears to be the explanation of a case quoted by Reid (1931)

> A man was shot in the right thigh on August 13th, 1924, and eight days later an expansile tumour with thrill was present On Sept 30th an operation was done, the heart being reported as in good condition In 1928 a recurrence of the arteriovenous aneurysm was found, the heart was now fibrillating and general anasarca present On July 12th, 1928, a second operation was performed successfully The cyanosis, venous engorgement of neck disappeared, and the heart gradually reduced to almost normal size

The same writer also states that excision of the arteriovenous fistula may restore a heart to complete efficiency

The following five cases are of some interest as indicating (1) the frequent, if not constant, association between persisting arteriovenous aneurysms and subsequent cardiac changes, of greater or less extent, (2) the period elapsing between the development of the aneurysm, and the occurrence of symptoms due to cardiac changes, and (3) the progressively serious deterioration of the heart, and conversely the chance of improved prognosis if early removal of the aneurysm is successful, even after the cardiac changes have been initiated

I regret that the notes on the cases are brief and curtailed, and leave many lacunæ on desirable observations, such as those as were made in the study of a similar series by Lewis and Drury, and described in their illuminating report Recognising these deficiencies I still felt that these records, embracing a period of nearly twenty years, might have some value as regards prognosis and treatment

ANALYSIS OF CASES

Case 1 —Arteriovenous (A.V) aneurysm of right thigh. The date of injury was Oct 17th, 1918, when the patient accidentally wounded his right thigh In patient treatment of seven days was required, the wound being ¼ in. in extent—depth unknown The A V aneurysm was not diagnosed until May 27th, 1934 (16 years later), when the heart showed only slight enlargement From 1919 however, the man had had medical treatment for dyspnœa for which there was no adequate explanation, and at intervals from then until 1934 had received treatment for a slightly dilated and rapidly beating heart In 1934 he consulted a cardiac specialist who found the A.V aneurysm. The heart was enlarged with tic tac rhythm. Pulse rate 116 standing, 100 lying Blood pressure 130/90 X ray examination showed heart with transverse measurement 5⅛ in. The urine contained a trace of albumin. The femoral artery was ligatured and the last report in 1936 indicated some improvement, though the blood pressure was higher (170/120) but with normal arteries Subjectively the cardiac symptoms had improved

Case 2 —The popliteal arteriovenous aneurysm from gunshot wound developed in 1918 in the right leg and was at once recognised No operation was performed By 1922 there were cardiac symptoms and enlargement of the heart was recognised but the early changes must have been present considerably earlier Between 1922 and 1930 signs of valvular disease became manifest In 1924 a thrill was detected over the apex. In 1928 the apex beat was ½ in outside the nipple line, and there was a systolic bruit In 1932 his right leg became swollen and painful The condition of the heart was as before but with bronchitis supervening Amputation was considered inadvisable owing to the state of the heart and chest, and the patient died in 1934 from rupture of varicose veins

Case 3 —Gunshot wound in left groin in November 1917 Early in 1918 an arteriovenous aneurysm in the left femoral was diagnosed. No operation was carried out By 1921 enlargement of the heart was clearly evident, and by 1931 the compensation had broken down bruits had developed at the mitral and possibly aortic orifices, and the prognosis was grave By 1936 there was total disablement Sclerosis of valves may have been present with a somewhat similar origin to sclerosis of proximal arteries described by Osler

Case 4 —The patient had a gunshot wound of the left arm on July 1st, 1916 and an A V aneurysm had developed by August 16th. Three operations for excision and ligature were performed (August 28th, Nov 10th, and Dec 4th) but without success By 1920 cardiac dilatation and systolic bruit at the apex were present, the latter being ¼ in. outside the nipple line The patient said he had been subject to giddiness and fainting attacks from 1917 Deterioration was slow In 1935 no material change had taken place in the heart and he was still subject to palpitation and dyspnœa Blood pressure 130/85

Case 5 —On April 24th, 1917, the right thigh sustained a gunshot wound close to the great trochanter, with a second smaller wound at the inner part of the right groin A foreign body was removed from the larger one which was found to extend to the bone By May 24th the wounds were reported as healed but an A.V aneurysm had developed between the femoral artery and vein. A machinery murmur and thrill could be heard and felt over a wide area, but no further operation was attempted. Function of the leg remained good except on much exertion but within six months a plexus of veins developed at the back of thigh and knee In 1920 heart sounds were stated to be normal but by 1921 there was a systolic aortic bruit and afterwards a mitral systolic bruit The man, however did not complain of dyspnœa until early in 1923 when the apex beat was in the nipple line with an apical systolic bruit and thrill The blood pressure was 120 The aortic murmurs seemed to have disappeared. By 1924 there was considerable deterioration with cardiac irregularity and palpitation obvious to the patient He remained in much this state until 1932 when the dyspnœa increased and was accompanied by precordial pain Death took place after a sudden collapse when the man was taking a short walk.

CONCLUSIONS

1 From an analysis of these cases it appears that cardiac changes depend to some extent in time of onset and severity on the type of arteriovenous aneurysm and its amenability to operation Early cardiac changes probably date from the establishment of the aneurysm but do not necessarily cause symptoms for a few years Systematic examination of the heart however would bring these changes to light if the probable developments were more fully recognised A late involvement of valves of sclerotic character is likely in progressive cases This was in two cases the main factor in termination of life (16 and 18 years after the original injury) and of causing total disablement in a third case (10 years after the injury).

2 Early surgical treatment for removal of the arteriovenous aneurysm or its obliteration by ligature is strongly to be advised on medical grounds apart from surgical considerations in order to prevent the cardiovascular changes which are almost inevitable sequelæ and an increasing cause of disability

My grateful acknowledgments are due to Dr J H Hebb director-general of medical services Ministry of Pensions for permission to publish these records

MEDICAL SOCIETIES

BRITISH INSTITUTE OF RADIOLOGY

AT a meeting of this institute held on Jan 14th the president Prof J A CROWTHER being in the chair a paper on

Cerebral Arteriography

was read by Dr H W DAVIES A certain amount of work on cerebral angiography had he said been done in this country but very little had been heard of it. Cerebral tumour was a sufficiently distressing disease to make any weapon of investigation a thing not to be ignored Cerebral angiography had been first attempted by Egas Moniz of Lisbon in 1929 after two years experiments on animals and corpses In 1931 one of his colleagues Dr Almeda Lima had demonstrated it in London at the National Hospital Queen-square using sodium iodide as the radiopaque medium This salt was opaque enough for the purpose but had proved too risky when there was any arterio-sclerosis Thorotrast was now used injected into the common carotid artery after its exposure through a small cervical incision The operation was performed in the theatre under local anæsthesia, after a general sedative Lateral views only were necessary in most cases The surgeon used a long curved needle of not too large bore as the artery lay somewhat deeply in the wound The amount injected was 10–12 c cm for the arterial system or 16–17 c cm for the venous system Some force had to be used to get the rather viscous thorotrast through the narrow needle so the surgeon must have all possible freedom of movement and be able to steady himself The first film was taken when about 10 c cm. had passed out of the syringe and the exposure must be short about 1/10th sec The head must be centred on the cassette before the injection started Shock proof apparatus was most desirable Thorotrast did not mix intimately with the blood and so the veins could be visualised By means of a new apparatus cassettes could be slid under the head and six films taken at intervals of a second From the blood stream thorotrast was eventually picked up by the cells of the reticulo-endothelial system In view of the amounts formerly used for visualisation of the liver and spleen it might be said that the small doses used for radiography were reasonably safe One objection was that its continuing radio activity might ultimately produce fibrosis in the reticulo endothelial system. It was imperfectly eliminated and remained in the system for years and might become partially converted into mesothorium and radiothorium Cerebral arteriography should therefore not be lightly undertaken, but the conditions in which it was applicable were sufficiently serious to justify the slight risks

The first discovery made had been that the blood supply of the brain passed to it much more quickly and in greater volume through the internal carotid artery than did the blood flowing to the superficial tissues by the external carotid The superficial vessels therefore did not obscure the intracranial ones until some seconds after an injection into the common carotid. Probably this was due to the size of the capillaries, which were larger and more numerous and also more dilated during mental excitement, than the general body capillaries Another factor was the anatomy of the external carotid which soon gave off a number of large branches The only immediate small branch of the internal carotid was the anterior communicating artery which in fact rarely appeared in the arteriogram In effect the external carotid was like a river delta. The internal carotid described a complicated system of curves which had diagnostic importance According to the anatomical text books it first curved back and then ran forwards again, but this was seen arteriographically in 30 per cent. of cases only and in 70 per cent it formed a complete S and then divided into anterior and middle cerebral the latter splitting almost at once into three branches which formed one of the best landmarks the Sylvian group The curves of the parent trunk had been termed the carotid syphon The ophthalmic and the anterior choroidal arteries might also prove of diagnostic importance The communicating arteries were not often seen, but the posterior part of the circle might be visualised by injecting thorotrast into the subclavian artery by a small subclavicular incision and compressing the artery beyond the point of injection Regurgitation of blood drove the thorotrast back into the basilar trunk which would be found to rise almost vertically from the base of the skull.

Abnormalities of the vessels themselves and of their position were the diagnostic points made apparent by arteriography Their grouping would sometimes indicate the tumour, and some tumours had greater blood supply than others Frontal lobe tumours showed absence of the upper bend of the syphon so that the curve was a U open posteriorly The whole Sylvian group was pushed downwards, and the anterior cerebral was displaced backwards and downwards A tumour in the front would push the Sylvian group somewhat downwards, but the displacement was still more marked if the tumour was situated further back. Midline tumours tended more to displace the syphon downwards so as to give a very marked curve to the anterior cerebral and pericallosal arteries The Sylvian group was pushed upwards and widely separated by suprasellar tumours and the internal carotid displaced sideways Temporal tumours pushed up the Sylvian group, leaving a margin round the tumour, and narrowed the syphon Deep temporal tumours displaced the vessels towards the observer in a lateral view, and also widely spaced the Sylvian group More superficial temporal tumours might obliterate the syphon Posterior temporal growths would leave the syphon alone A small tumour might not cause any displacement

Vascular tumours like angiomas had large looped vessels of supply to them, and they themselves showed as coiled masses of blood-vessels Meningiomas had normal sized vessels of supply

Arteriography was also useful in intracranial aneurysms These were usually larger than would be expected from the film and filled with blood clot They appeared as rounded opacities

DISCUSSION

Dr **Duncan White** said that a few years ago he had done some cases, one of which he would show Originally the external carotid had been clamped—apparently quite unnecessarily He asked if the liver and spleen of any patients had been examined at a later autopsy The spleen of patients after hepatolienography had been found sufficiently radio active to fog a film Arteriography could not be regarded—at any rate in this country—as an out patient procedure In what proportion of cases, he asked had it given information that could not be obtained by direct radiography or ventriculography ? The *case he showed represented an intracranial aneurysm* diagnosed in this country in January, 1933

Dr **G E Vilvandré** said that arteriography involved very highly skilled work on the part of the surgeon, and should be reserved for cases where the diagnosis could not be made by other means He had been startled at the force used by the young surgeon keen on getting a diagnosis The results of the method were, however, impressive Aneurysm was an important field in which arteriography was justified, but cerebral tumours in a large proportion of cases could be revealed by direct radiography A good clinical examination was also essential. He hoped that the paper would not lead small hospitals all over the country to try to produce arteriograms

Dr **M. H Jupe** agreed that arteriography should be confined to lesions connected with the vessels Tumours at the base might not give any clue through the vessels Second pictures gave a better view of meningiomas than early ones

Dr **G Simon** mentioned the possibility of failure due to the injection being made too slowly He took his first film after 10 c cm had passed in, and another three seconds later

Dr **R McWhirter** said he had seen aneurysm successfully shown up The photograph was usually taken after counting six A Potter-Bucky diaphragm had considerably improved the results

REPLY

Dr **Davies**, in reply, said that the injections into the common carotid had not had any ill effects on the results He had never examined the spleen of a patient on whom he had done an arteriogram. He knew of one case where a hepatolienography had had no ill effects seven years later Only about 12 c cm. of thorotrast were used in most cases, as the second side was not injected unless it appeared necessary No arteriography had been carried out in his department unless a ventriculography had already proved of no value Only about thirty cases had been done altogether

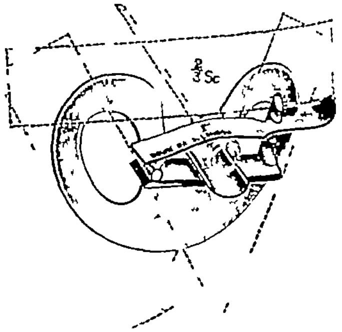
NEW INVENTIONS

PNEUMOTHORAX NEEDLE-HOLDER

During pleural washouts or the treatment of spontaneous pneumothorax it is desirable to keep the needle securely fixed into the chest wall, for, owing to respiratory or muscular movement, it is liable to lateral displacement and may work itself out of the skin



These defects are entirely overcome by using a small device that consists of a slightly concave base with lateral fenestrations, from the centre of which projects the needle support and spring catch for instant adjustment or fixing The holder is secured to the chest wall by strips of adhesive plaster as shown in the illustration

I recently used a similar instrument in a case of spontaneous pneumothorax with valve action, and the needle was kept in position for ninety six hour

This appliance is now being made by Messrs Down Bros , Ltd , London

David A Herd, L R C.P Edin
Late Assistant Tuberculosis Officer Stoke-on Trent

Kent and Canterbury Hospital —The erection of the new hospital on a site in the south of Canterbury is progressing and its total cost, together with the nurses' home is expected to be about £125,000, with an additional £22 000 for apparatus and equipment About £102,000 has been collected already

REVIEWS AND NOTICES OF BOOKS

Urological Roentgenology

By MILEY B WESSON M.D Ex President American Urological Association and HOWARD E RUGGLES M.D Roentgenologist to University of California Hospital St Luke s Hospital and Clinical Professor of Roentgenology Univ of California Medical School London: Henry Kimpton. 1937 Pp 260 22s *6d*

THE publication of a work of this character was suggested as long ago as 1923 Since that time members of the American Urological Association have assisted the editors by sending to them films characteristic of various urological conditions accompanied by case histories and operative and post mortem findings As a result Drs Wesson and Ruggles have been provided with a superb collection of radiograms Plates selected from this collection form the basis of the present volume The aim has been to reproduce those most characteristic of the various urological conditions that the practitioner is likely to meet For this reason attention is paid less to rarities than to commonplace lesions Perhaps the most interesting chapter in the book is that dealing with renal tuberculosis the editors are strongly of the opinion that the danger of pyelography in the presence of renal tuberculosis has been over-emphasised, and that urography may be the only means of arriving at a diagnosis in certain cases They illustrate this by plates showing various stages in the progress of renal tubercle Another section which is remarkably complete is that which deals with solitary cysts of the kidney This condition is not as rare as some works would suggest and a study of the characteristic changes should make it possible for anyone unfamiliar with the lesion to diagnose it in a pyelogram

The text is clear and restrained just sufficient to allow the reader to interpret the plates As in all condensed writing statements appear which may sound dogmatic such as that hypertrophy of the psoas muscle may result in a distorted hydronephrotic pelvis, but this is perhaps inevitable in this form of literature. We warmly recommend this work to all who require a comprehensive survey of X rays in urology

Physiological Principles in Treatment

Seventh edition By Sir WALTER LANGDON BROWN and REGINALD HILTON London Baillière Tindall and Cox 1936 Pp 308 10s *6d*

IN the last decade our ideas have undergone fundamental alterations on many points of cardinal importance in physiology The same period has seen a much wider use of exact scientific methods in clinical work Those sentences are from the preface not of this but of the first edition of a book which was written in 1908 as a series of chapters on applied physiology intended to show the student or the busy practitioner how far physiological facts and principles pointed the way to rational treatment or provided rationale for treatment long justified by the results of its empirical use The chapters have changed their content a good deal in successive editions and in this one their general plan alters a little too Vitamin now stand alongside the hormones ketosis comes into the same chapter as diabetes destructive criticism of such ill founded theories as those relating to intestinal toxæmia can now the authors think be safely curtailed the section on asthma is extended to include some other allergic manifestations and a new chapter on the anæmias appears Through these changes the general purpose of the book remains unaltered It brings the physiologist to the bedside and mobilises his contribution especially his more *recent contribution to treatment It is written for* the intelligent practising doctor not for the specialist or the research worker and is therefore not overburdened with detail and not afraid in places of confident statement where the expert might prefer to hedge It is simple clear and readable Medicine has still much to learn from the physiologist s discoveries, and from his manner of thinking so we share with the authors of this book their hope that in its new form it may continue to serve its useful purpose

The Operations of Surgery

Eighth edition By R P ROWLANDS M.S F R C S late Surgeon to Guy's Hospital; and PHILIP TURNER, B Sc M S F R C S Consulting Surgeon to Guy's Hospital. London: J and A Churchill Ltd Vol. II 1937 Pp 998 30s

FOR the second volume of this splendid text-book of operative surgery which includes all the surgery of the trunk, the assistance of other writers has been invoked. Mr W H Ogilvie has revised the sections upon spleen hernia pancreas rectum and surgical *preparation* Mr *Ralph Thomson has written on* genito urinary operations Mr G F Gibberd on pelvic operations in women and Mr R C Brock on thoracic surgery There will be some regret at this multiplicity of authorship for it brings the book into danger of losing just those qualities especially the feeling that it voiced the mature views and sound judgment of two surgeons, which gave confidence to those who followed its precepts The reader can no longer open it with the same conviction that he will be adopting a wise course by following its advice The book is becoming more a compilation of operations and methods without that guidance which has hitherto been the secret of its popularity *and success And even for this purpose it fails for* no one could carry out a Harris s operation for removal of the prostate from the description found on page 720 It shakes our confidence to read of operations for removal of the vesiculæ seminales for tuberculous epididymitis and to see the many years old diagram depicting the lymphatic spread of carcinoma of the rectum when modern research both at home and abroad, has made it clear that when a growth in this situation is removable there is no downward spread or extension to the ischiorectal fossa and hence no reason for removing the rectum for more than 2–3 cm below the growth. We cannot find in the book how to deal with a uretero vaginal fistula which has formed after a Wertheim operation and we do not think that the assessment of the value of gastrojejunostomy for duodenal ulcer reflects the general view of physicians or surgeons to-day

Having said these things we gladly testify that there is much of a practical nature and common sense in this book which is difficult to find elsewhere The descriptions of operations are clear and precise difficulties are noted and causes of failure suggested If the character of the original work has been changed it is true to say that the book ranks high in surgical literature and we have no doubt that it will continue to be a standby to junior surgeons in grappling with the many operative problems they meet

An Introduction to General Practice

By E Kaye Le Fleming, M A, M.D, Chairman of Council, British Medical Association, Direct Representative, General Medical Council Chairman of the Conference of Local Medical and Panel Committees, 1925–30, Chairman, Representative Body, B M A., 1931–34 London Edward Arnold and Co 1936 Pp 150 5*s*

None could be better qualified than the author of this book to teach the young doctor starting general practice what he should know about it and in so far as the written word can even take the place of practical experience, Dr Le Fleming has, in the main, succeeded in his task. Here will be found much shrewd advice upon N H I and contract practice, midwifery, drugs and the chemist, finance, the law, and that unique relationship which exists between the general practitioner and his patients The essential difference between hospital and private practice is clearly and accurately defined "In the hospital [the doctor] is omnipotent, the patient a slave who must take the treatment offered and accept it as the best—or leave In practice the position is reversed The patient is the master and the doctor a paid adviser The patient may take as much or as little of the advice offered as he wishes, may question its quality and change his adviser at will." Dr Le Fleming's frank remarks on professional deportment savour of the last century We are told that because many patients dislike the smell of tobacco the doctor should not smoke till his day's work is over (whenever that may be), and that in no circumstances should the doctor, until he has removed his overcoat, approach the sick room There is surely plenty of evidence that the personality of the doctor soon overrides these trivial things and that many a general practitioner may be as well beloved for his unconventional behaviour as for his skill and kindliness There is an amusing misprint on page 120 where "waiting rooms" are described, with a good deal of unconscious truth, as "waiting tooms"

Man, The Unknown

Popular (second) edition By Alexis Carrel London Hamish Hamilton 1936 Pp 318 6*s*

In this book the author attempts, he admits imperfectly, to analyse and interpret man in the light of the relevant facts about him furnished by the various branches of natural science, among which he includes psychology, although denying, perhaps with some truth, that this study is as yet worthy to be called scientific In attempting so large a task within so small a compass, Dr Carrel has been compelled to adopt a dogmatic method and to confine himself to making a large number of what he describes as approximately true statements but which are, in fact, very often his own conclusions, many of which are highly provocative and controversial Indeed, there is material for argument on almost every page The latter part of the book deals with the remaking of man and attempts somewhat vaguely to synthesise him on sounder lines Modern industrial conditions, thinks Dr Carrel, and few will quarrel with him here, crush individuality and standardise mankind to a poor pattern The remedy, he suggests, lies in a return to a vigorous life of physical hardship and mental self discipline "Culture without comfort, beauty without luxury, machines without enslaving factories science without the worship of matter, would restore to man his intelligence, his moral sense, his virility, and lead him to the summit of his development" Too much useless effort, he maintains, is being expended in trying to strengthen the weak. Our object should be rather to strengthen the strong and so breed a "non hereditary aristocracy" of mentally and physically superior persons who "could effectively help the weak." But might it not follow that such an aristocracy of the strong would become arrogant and despise the weak without wishing to help them?

Dr Carrel discriminates sharply, and it may be wondered upon what evidence, between the potentialities of the male and female brain He is no feminist but believes that woman's primary function is the bearing and rearing of healthy children to which end he would have infant welfare taught in girl's schools With the problem of the unmarried or sterile woman he wisely refuses to wrestle The reader may feel that the author's constructive notions suggest a grim, humourless efficiency savouring too much of totalitarianism for the English taste Nevertheless the book is an important one written in a simple and readable style

Absorption from the Intestine

By F Verzar, Professor of Physiology of the University of Basle, assisted by E J McDougall, Ph.D London Longmans, Green and Co, Ltd. 1936 Pp 294 21*s*

This admirable book is the seventh of the monographs on physiology which were for eleven years edited by the late Ernest Starling The present volume appears with a general preface by Prof Lovatt Evans, and we welcome the knowledge that the series is to be continued under his ægis The subject of absorption from the small intestine is of high complexity but great importance to physicians, and not only those who are especially occupied with gastro enterology, but those whose work brings them in contact with tropical medicine and disorders of the endocrine system will read this volume with interest and profit Particular reference must be made to the discussion of the absorption of water and the illuminating passages dealing with the influence of the cortical hormone on the absorption of sugars. Prof Verzar has long enjoyed the reputation of a master of this subject, and this will be enhanced by the present work which is adorned by many illustrations and includes a first-rate bibliography

Roentgenographic Technique

Second edition By Darmon Artelle Rhinehart, A.M., M D, F A C R, Professor of Roentgenology and Applied Anatomy, School of Medicine University of Arkansas London Henry Kimpton. 1936 Pp 431 28*s*

With advancing knowledge in radiology, increasing attention is being paid to detail in order to differentiate between lesions giving somewhat similar appearances, the demand for better quality films has resulted in more importance being placed on radiographic technique This book admirably meets these requirements and the information is supplied in a practical form It would be safe to say that where difficulty is being experienced, one could almost certainly obtain not only the cause of the error but also the correction of this in the appropriate section. The diploma course in radiography has recently been extended to two years and a book of this type is much required, it will be useful to radiologists who wish to improve the quality of their work and to students of radiography

THE LANCET

LONDON: SATURDAY, JANUARY 23 1937

THE FACTORIES BILL

THE long promised Factories Bill will be laid before Parliament during the early weeks of the session which has just opened Even that, maybe is not quite certain and until the Bill is printed no one outside the departments concerned can do more than guess at the nature of its provisions But speculation is not without a guide we may presume that the new Bill will be based upon the provisions of the Bills of 1924 and 1926 which failed to reach the Statute Book. We must not expect any proposals for widespread or profound alterations in factory legislation but we shall at least find one great boon namely a serious and a consistent attempt to simplify and to codify the existing Acts regulations and orders in which our present factory legislation is embodied —*should we say entombed?* The present confusion in the written word breeds trouble uncertainty and irritation both in industry itself and in its medical supervision. On the analogy of previous Bills we are also entitled to predict a concerted effort to raise and to define at a higher level, some of the basic minima to which a healthy factory must conform There is an appalling gap between the daily routine of progressive firms and that of competitors who regard as lawful anything that does not actually violate any existing order or regulation So long as this state of affairs endures both enlightened employers and well organised groups of workers are placed at a serious economic disadvantage We should like to think that the hours of work in unregulated and casual occupations will be brought under control that overtime will be abolished for all young persons and without exception and that some limit will be set to the overtime-employment both of men and women in industry In his annual report for 1935 the chief inspector of factories related as he had often done before the serious effects of excessive overtime every doctor who has practised in an industrial area has railed against this evil. It is perhaps not unreasonable also to hope that minimal standards will be laid down for many if not for most, of the basic factors in good industrial hygiene—viz. heating lighting and ventilation—and that welfare problems will receive the attention they require Our own profession will anxiously scan the steps proposed to improve and develop the medical and nursing services in industry

Our readers would do well to obtain two communications which have reached us The first is entitled The Provisional Programme of the Factories Bill Campaign[1] the second issued by the Open Door Council[2] is simply called The Factories Bill 1937 The former contains a reasoned series of suggestions which it hopes to find embodied within the new Bill the latter argues cogently for a modern and scientific measure which will give equal and equally good conditions of work to men and to women workers While they are at it might not these bodies of active citizens also give some attention to the Workmen's Compensation Acts which are in a comparable state of chaos?

MIXED BACTERIAL MENINGITIS

DOUBLE infections of the meninges are uncommon. Thus among 442 cases of meningitis in which organisms were identified TRIPOLI[3] found only 2 examples both were fatal and in both of them *Hæmophilus influenzæ* (Pfeiffer's bacillus) was isolated—once with a staphylococcus and once with a pneumococcus In the same series there were 221 cases of meningococcal meningitis with a fatality rate of 65 per cent, and 22 cases of streptococcal meningitis with a fatality rate of 92 per cent CADHAM[4] writes that the proportion of deaths in the latter condition is apparently 97 per cent and quotes H GRAY who was able to find only 66 recorded cases of recovery in 6 of which the patient had scarlet fever

Though streptococci may no doubt reach the meninges via the blood stream or through the perineural sheaths of the olfactory nerves they usually come from the middle ear or (less often) from the nasal sinuses In the case he reports on p 198 Dr CUNNINGHAM regarded the streptococci as secondary invaders—a finding he considers usual—and his opinion that the left mastoid was their source can scarcely be disputed since organisms of the same serological type were isolated first from the mastoid antrum and later from the cerebro-spinal fluid In this case it is clear that although drainage and intensive anti meningococcal serotherapy might have prevailed against the meningococcus alone the advent of the hæmolytic streptococcus—against which anti streptococcus serum appears to be of little or no value'—made the outlook virtually hopeless The fatal issue was in any event determined by the streptococcus but it is interesting in passing to note that Dr CUNNINGHAM employed meningococcal antitoxin the value of which is not yet established whereas most clinicians would probably have preferred antibacterial meningococcal serum especially now that the Lister Institute issues a special serum for use in infections by Group II the strain usually found in the basal meningitis of infants CUNNINGHAM rightly emphasises the importance of a complete bacteriological examination of the cerebro-spinal fluid obtained with rigid aseptic precautions whenever acute mastoiditis is accompanied by signs of meningitis and before any operation is attempted If the meningitis is purely meningococcal, conservative measures he believes will suffice for the treatment of the mastoiditis, if on the other hand the infection is mixed, antimeningococcal therapy must be combined with immediate operation on the mastoid, but unless there is clinical evidence of an intracranial abscess the membranes of the brain should not be opened.

To day, fortunately, there is reason to hope that the prognosis of a desperate condition, whether due to meningococci or streptococci or both, may improve with the use of Prontosil or its derivative *p* aminobenzenesulphonamide On Dec 5th we wrote of the imperative duty to employ these preparations not only in puerperal fever but also in other severe forms of streptococcal infection, and since then (Jan. 2nd) Mr H PROOM has reported in our columns that *p* aminobenzenesulphonamide, injected immediately, will protect mice against about a million minimal infecting doses of the meningococci, whether of Group I or Group II Although, as PROOM remarks, the conditions in established cases of meningococcal meningitis in man are by no means comparable with those following intraperitoneal injection of culture into mice, the results of his experiments suggest—and we would add, demand—clinical trial of the drug, especially as he says that "cerebrospinal fluid taken from rabbits which have received large doses of the drug inhibits the growth of a small inoculum of streptococci, whereas a similar number of streptococci grow freely in the normal fluid" Streptococcal and meningococcal meningitis should thus be added to the list of conditions in which one or other of these new therapeutic weapons should be brought into action. On p 194 Mr A T FULLER, D Sc, describes fresh inquiries into how they work.

BURIED TREASURE

WE have already reviewed[1] the work of the Board of Control (Lunacy and Mental Deficiency) as set out in its report for the year 1935 This annual report is an index of progress made during the year and is eagerly scanned by all who are interested in mental care But the Board issues a supplement to this report in the form of a non-statistical review of what is being done at the mental hospitals The current volume[2] covers laboratory and other routine, research, clinical odds and ends, and the individual reports by the Board's commissioners of what they found and recommended on their visit to each institution. The perusal of this rather heterogeneous collection is likely to reassure anyone who fears that the comfort and the health of patients are neglected in mental hospitals or that there is little clinical investigation, treatment, or research

This in itself is no mean service, but unfortunately the book has not been indexed or properly edited, and many interesting communications are buried in it This applies to some modest or provisional reports such as J E Howie's trial of manganese chloride in the treatment of dementia præcox (p 88), Haslam Fox's use of Evipan sodium in continuous narcosis (p 119), Ann Evans's study of an outbreak of dysentery (p 117), and the similar investigations from fifteen other hospitals, the three accounts of the effect of large doses of atropine sulphate upon post-encephalitic parkinsonism (pp 86, 95, 175), and Denis Williams's research into the innervatión of the cerebral vessels. On some subjects—e g, the treatment of G P.I., Sulfosin and Pyrifer therapy in schizophrenia, Somnifaine narcosis, cholesterol estimations—there are many reports, indicating much rather ill-coördinated activity which is less fruitful than it might be, the number of patients observed is in many instances too small to warrant conclusions, and a normal or control series is not mentioned. If such research were planned and carried out in concert by a group of hospitals, instead of sporadically as at present, many a dubious question could be settled or, at any rate, could receive more than a hesitating clinical impression as its answer. Scattered through the Board's report, however, there are also references to work that has been already reported in medical and other scientific journals Most of this necessarily comes from centres, like the Maudsley Hospital (p 110), Cardiff City Mental Hospital (p 78), the Royal Eastern Counties Institution (p 208), and Stoke Park Colony (p 211), which have research as one of their chief objects and are appropriately staffed, but there is much evidence of high scientific standards among investigators in institutions less well equipped for the purpose

The opening summary (p 9) indicates the range and the chief topics of inquiry Noteworthy is the volume of research at institutions for the care of mental defect, especially those of the London County Council, in addition to the two (at Colchester and Bristol) already mentioned There are in the volume also some hitherto unpublished case-reports—e g, encephalomalacia (p 138), pontine hæmorrhage (p 95), suprarenal tumour (p 140), agranulocytosis (p 146), progressive lenticular degeneration (p 158), pellagra (p 182), herpes zoster (p 187), and renal glycosuria (p 188) It may be questioned whether some of these, even if they were more accessibly printed, would serve much purpose in their present brief and incomplete form, like some of the unpublished research here communicated they obviously do not reach the standards exacted by scientific journals Nevertheless they are of interest to other workers and would benefit by the expert scrutiny and appraisal which publication usually entails It may be that there is room for a modest clinical journal for psychiatrists which would not be averse from publishing isolated case-reports and inconclusive pieces of research. In any case it is surely undesir only medium chosen should be an un indexed official report of which no account is taken in the Cumulative Index, the Zentralblatt or any of the other means of reference that psychiatrists use Much of the valuable material in this blue book may remain buried, and it is under this impression that a number of page references is supplied here

ANNOTATIONS

MISLEADING LABELS

LABELS are supposed to indicate the nature of e thing labelled, but Dr James Fenton calls atten on[1] to their widespread use to mislead and deceive ose who buy labelled food It is true that the ood and Drugs (Adulteration) Act of 1928 contains ovisions intended to protect the public in the atter of labelling of food but these provisions also ntain clauses intended to guard the seller against xatious prosecution and this makes them difficult enforce. It is not easy to prove that a false label wilfully given knowing it to be false and it is easy print on a label matter which although distinct nd legible is so inconspicuous as not to be noticed y the buyer in the ordinary course of shopping eople neither stupid nor unusually ignorant might ot realise that Wood table vinegar is made by luting and colouring acetic acid formed by destruc ve distillation of wood or that no wine made in ritain is entitled to be called sherry A subtle eans of avoiding the dangers of the law is by what r Fenton calls the collateral advertisement n extravagant puff in the form of newspaper adver isement handbill or radio broadcast which creates ho desire to buy whilst the label, to which the ustomer gives little attention may be moderate in ts claims and legally safe Dr Fenton reviews the ecent experience of the Royal borough of Kensington n regard to articles sold under misleading descrip ions Jam is an article that is very liable to adultera ion and improvement Good fruit is not always btainable at a low price and various materials uch as apple pulp pectin from various sources and ruit juice are used to enable jams to be made con aining low proportions of their titular fruits The Food Manufacturers Federation in 1931 after con ultation with the Society of Public Analysts issued standards for two grades of jam the first quality containing from 45 to 30 per cent of the named fruit according to its nature and the lower quality 20 per cent. with in this case the declaration on the label With other fruit juice The Kensington authorities have found cases where the second quality has been labelled so as to lead the customer to think that it is first quality although it could be contended that careful reading of the label would show that it was not Sweets drugs wines infant and invalid foods and many other classes of food materials are discussed in the article which shows a widespread attempt to defeat the object of legislation intended to protect the public It is difficult to suggest remedies But if specific legislation is ineffective some provision should be made for courts to decide what are equitable dealings as between buyer and seller regard being had to the ordinary conditions of life and these do not allow the busy housewife to take her legal adviser with her when shopping or even to study the label on every article she feels like buying while a row of other customers is waiting to be served

SUPPLY OF SPECTACLES

IN ophthalmic clinics there are at present two methods by which patients may obtain glasses Either an optician appointed by the managing board attends the patients at the place where the eye examination is conducted or the patient takes a prescription to an outside optician The Central Bureau of Hospital Information has made an inquiry into the working of the two systems and has tabulated the replies in one of its useful series of memoranda[1] Certain advantages and disadvantages inherent in both systems may be considered under the heads of optical personal and administrative. From the optical point of view it is obvious that an optician working at a clinic under the direct supervision of an oculist must maintain a recognised standard or give place to a better man That such a standard is of vital importance is patent to ophthalmologists but not so obvious to patients or lay bodies There are almost as many grades of lenses as there are of cloth responsible opticians by long training, know how to select and reject imperfect lenses The discards are accepted by opticians who have not such training or who specialise in cheap work. Often there are several ways in which the optical prescription can be dispensed that most suitable to the patient and his activities can only be selected by a competent optician sometimes with the collaboration of the oculist The frames supplied require careful selection; presuming that they are of good workmanship the optician has to consider the type of work and habits of the wearer before advising any particular style Often the oculist can be of greater service to the patient if he can have the benefit of suggestions from the optician at the time of his examination He can see the effect when the glasses are put on and suggest minor alterations From the patient s standpoint the knowledge that the work and charges of the optician are under professional supervision should weigh heavily Patients taking prescriptions away from the clinic have the advantage of being able to choose their own optician but they run the risk of being persuaded to buy unnecessarily expensive glasses Some of these points are illustrated in the remarks printed in the memorandum from one of the hospitals at which an optician attends

> Under this arrangement the hospital knows precisely what the patients are charged. Previously there were instances of patients taking the ophthalmic surgeon s prescription to an optician and having to pay excessive charges It was also found that certain patients having received the advantage of free consultation with the ophthalmic surgeon purchased a very expensive pair of glasses, and it was felt that this was not right
>
> In the first instance one or two objections were made by patients who wished to obtain their glasses privately but it was pointed out that the prescription was the property of the hospital and could only be used for the supply of glasses by the hospital opticians
>
> The hospital is entirely satisfied with present arrangements and is inviting tenders each year Preference is given to firms which only supply glasses to the public n a qualified medical officer s prescription

Obviously it is a good arrangement for the optician to be in attendance at the clinic, but certain administrative difficulties arise Though an optician may be willing to rent a room from the hospital there may not be one available Where hospitals are mainly dependent upon local contributions there may be a feeling against the selection of a particular optician which will result in loss of subscriptions The difficulty is not diminished when opticians have seats on the board of management. Remarks supplied by hospitals at which an optician does not attend and given in reply to a questionnair which will be found in the memorandum, may make the position clearer

---

[1] Med Offr January 1937

[1] Memo No 107 From the director of the Bureau 1 Grosvenor-crescent London S W 1 1s

The ophthalmic surgeons have proposed that an optician should attend at the hospital, but the board have always adhered to the principle that the patients should have free choice of opticians, and no member of the hospital staff is allowed to recommend any particular optician

The practice of allowing patients attending the ophthalmic department to choose their own optician was adopted at the request of the local optical society

The prescription is the property of the hospital It must be used only for the dispensing of glasses in accordance with a scale of charges agreed to and approved by the committee This practice works very well and enables all opticians to have a portion of the work.

Each year a local firm is selected by tender to supply lenses and frames Measurements are taken by a member of the hospital staff and the patient selects the frame from specimens kept at the hospital The prescription, particulars of the frame selected, and measurements are then sent to the firm which obtained the contract They supply the glasses within one week

The self contained clinic may be the ideal solution but not always easy of attainment

THE PERIPHERAL CIRCULATION IN SURGICAL SHOCK

THE cold clammy skin and greyish pallor symptomatic of shock are evidence of deficient peripheral blood flow Measurement of the change they cause in the peripheral circulation is therefore an index of the shock producing properties, for example, of pain, fear, cold, asphyxia, and intestinal obstruction From the Harvard Medical School comes a study,[1] based on observations on medical students and patients, in which a plethysmograph was used to secure graphic records of the circulation through the hand while the person at the other end of the arm was subjected to various abnormal stimuli. Observations were also made on patients during and after abdominal operations and in the state of collapse produced by intestinal obstruction Generally speaking, the effect of harmful stimuli is to decrease the peripheral circulation, this effect being due to vasoconstriction evoked through a sympathetic reflex Withdrawal of the stimulus is followed within a short time by a reactive hyperæmia, and this occurs also after removal of the compression of a tourniquet By measurement of the circulation in the hand Freeman and his co workers at Harvard were able to show that the hyperæmia balances the preceding deficiency of blood to the part oxygen loss in the tissues is thus rapidly replaced In patients with surgical shock the reactive stage develops imperfectly or not at all Vaso constriction remains, and the result is tissue starvation, which if widespread leads to death Freeman thinks that the evidence of other observers of surgical shock points to a general reduction of blood flow throughout the peripheral circulation, affecting the splanchnic area and the muscles in the same way as the hand He regards it as a dangerous exaggeration of the lesser, and primarily physiological reaction, whose aim is to preserve the organism by diversion of the blood to the internal organs

Circulation in the hand is affected by local stimuli as well as by changes affecting the whole organism, and the plethysmograph records were therefore taken with the hand kept at a constant temperature Prolonged exposure of the body to cold uniformly reduced the flow through the hand. The method adopted was to have the student lying very lightly clad on a bed for a considerable time, and then for a short time to open the windows wide Pain was tested by inflating a balloon placed in an ileostomy opening The actual insertion of the balloon produced no effect, but inflation was soon followed by decreased blood flow in the hand. In another patient, who had a permanent colostomy performed for malignant obstruction, permission had been obtained to insert and inflate the balloon on several occasions The effect of apprehension was tested by recording the reaction to a proposal to reinsert the balloon. This was as pronounced, though not as prolonged, as reaction to the actual inflation. Asphyxia, produced by inhalation of gases poor in oxygen, much diminished the blood flow through the hand. Manipulation of the intestine during operation also led to a fall in the peripheral blood flow, and in post operative shock reactive hyperæmia after removal of a tourniquet hardly occurred at all Improvement after intravenous infusion was, however, quickly shown by the plethysmograph. and as the shock passed off so did the peripheral vasoconstriction. Freeman writes of the fallacy of focusing attention on the blood pressure as an index of the efficiency of the circulation. Blood pressure, he says, is an expression of the amount of fluid in circulation and of the peripheral resistance A substantial fall of blood pressure was found in some cases in which the general condition was good and in which the peripheral blood flow was also satisfactory, yet in cases of profound shock blood pressure readings were sometimes near the normal Adrenaline and ephedrine, it is pointed out, are known to be ineffective in combating surgical shock.

PRACTISING MIDWIVES

THE Minister of Health has reminded local supervising authorities that their proposals for the service of salaried midwives should be submitted before the end of the present month We learn from a recent report[1] of the work of the Central Midwives Board that of the 62,064 names on the Midwives Roll at the end of the year only 16,165 were those of women actually in practice as midwives The number in practice it is true is 300 greater than in the previous year, but this must be set against an increase of 3100 in the number on the Roll. The C.M.B. estimates the proportion of trained midwives who practise as such to be only 26 1 per cent of the trained women on the Roll and the proportion diminishes each year The report alludes to the retirement of its chairman, Dr J S Fairbairn, and places on record its admiration of the immense efforts he made to improve the status of midwifery in this country Mr Arnold Walker has been appointed by the Midwives Institute to fill the vacancy so occasioned Apart from the essential figures in the report, interest attaches to some decisions on the etiquette and practice of midwifery given during the year It is now on record that the midwife, like the doctor, has the right to refuse any case which she does *not* desire to *attend*, but this does *not* apply to cases in which attendance may be demanded on humanitarian grounds or in which the midwife owes duty to some employing authority Inquiry having been made whether a midwife is expected to attend for at least ten days any case of abortion to which she has been called, the Board remarks that if it is not a booked case, and the doctor has been sent for privately by the patient or her friends a midwife may retire or may remain as a maternity nurse In reply to another inquiry the Board states that to give ergot at the end of the first stage of labour save in emergency is bad practice and such treatment is regarded as definitely outside the midwife s province The Board sees no objection whatever to the taking by midwives of any steps which may result in the resuscitation of apparently stillborn children Finally a nurse midwife employed by a district nursing association is bound to report to the local supervising authority should she be attending septic wounds or any other condition which may raise suspicion of infection

HOW CHARACTERISTICS ARE TRANSMITTED

To enable us to distinguish between the inherited tendencies and the environmental influences which together mould a developing organism is properly considered one of the most important tasks of biology in its relation to human welfare. In an address delivered on Tuesday last Dr David Forsyth endeavoured to persuade the Eugenics Society that it is a false issue to regard heredity and environment as separable entities we are wasting our time he thinks in analysing living organisms on this assumption. Dr Forsyth argued that the environment of a mammalian germ cell is the parent s body which begins to exert its effect immediately the germ cell is formed. The parent is however as much the product of inherited as of environmental influences The surroundings of the germ cell are therefore an inherited environment, and hence we cannot really distinguish between heredity and environment But surely Dr Forsyth lays himself open to the retort that he is using the word heredity in two different senses ? To the biologist the inherited constitution of an egg is that which is contained within it at its formation and which as experiment shows never deviates from a certain mean in its ultimate expression in spite of environmental changes An environment is not inherited in a biological sense but only in the sense in which property and traditions which are external to the organism can be inherited. For this biologists have unfortunately no separate word Though organisms certainly inherit (biologically) a tendency to produce a particular *type of environment* for their germ cells so far as the latter are concerned it is still purely an environment in which eggs of different hereditary constitutions can develop without losing their individual characteristics Dr Forsyth sought to reinforce his argument by pointing out that soon after development has started the embryo is mainly and probably entirely composed of substances derived from the environment so that there is nothing left of the originally inherited materials The biologist would reply that the essential things that are inherited are not certain substances but configurations of substances—patterns which persist as inherited characteristics though the original molecules which compose them are completely replaced by others from the environment These patterns require a certain range of environmental conditions in which they can express themselves and by which they can within limits be modified Dr Forsyth extended his desire for unification to the organism itself and its environment He showed that spatially no hard and fast line can be drawn between an organism and its environment; *the two imperceptibly merge into each other* and are continually interacting. No doubt this is true but it cannot prevent us from regarding an organism as a kind of focus around which certain configurations of matter are performing characteristic reactions This conception is not invalidated by the *fact that* the reaction system is not sharply demarcated *from* surrounding matter It is again these patterns and reactions which are the essence of the thing called organism the materials taking part in them are derived from the surroundings where these same substances are not behaving in this manner We have reasonable grounds for *differentiating between* a single organism and its environment, *although* as Dr Forsyth quite logically concluded each may be considered in a sense as part of a larger organism comprising all living things and their environments But while unable to follow Dr Forsyth in his conclusions or to find convincing evidence of their practical or theoretical value we admit that the question of heredity and environment is not as *easy* to define as many biologists and even medical men are *apt to assume*, and welcome the stimulus he has *given to consider clearly* what we mean by these terms.

GASTRIC ACIDITY

ACIDITY of the gastric juice is sometimes confused with its volume so that the terms hyperacidity and hypersecretion have even been thought synonymous Such confusion has arisen partly through difficulties in measuring the amount of juice secreted (unmixed with saliva, food or the contents of the duodenum) and perhaps partly because a highly *acid juice is* usually found in large, and an achylic juice in very small, quantities. Gradually however it has become clear that the hydrochloric acid of the stomach is secreted by the acid cells at a constant fixed concentration and that these cells cannot appreciably vary *its* strength. The variable factors are the number of cells actually secreting—and therefore the volume of acid put out—and the diluting agents of which in recent years the alkaline duodenal contents and the neutral or alkaline gastric mucin have been especially studied. Welin and Frisk[1] have lately recorded their estimations of the volume of gastric juice secreted in man obtained by a technique which excluded saliva and duodenal secretions Using as their stimulus to gastric secretion an intravenous injection of 20 units of insulin they found that an increase in acidity and an increased volume of juice followed in about 30–45 minutes; but there was no correlation between the degree of acidity and the rate of secretion—*in other words* the rate of secretion might drop while the total acidity remained almost unchanged In all the cases *of duodenal ulcer investigated the rate of secretion* was high the amounts varying between 200 and 600 c cm of juice in an hour as compared with 100 to 200 c cm an hour in normal subjects The acidity was found in these experiments to be in inverse relation to the amount of mucus and the conclusion is drawn that hyper and hypo acidity are merely terms representing varying *rates of* secretion of a juice of fixed (maximal) acid concentration altered by the diluting effect of gastric mucus This conclusion agrees with views of those who hold that the only means the stomach possesses of reducing its acidity is the secretion of mucus; duodenal regurgitation they say plays little or no part in this regulation Such investigations emphasise the significance of the volume of gastric juice secreted they suggest that hypersecretion and not hyperacidity is the essential consideration in conditions like duodenal ulcer, and that the gastric mucin is very important as adsorbent and acid regulator

EXAMINE YOUR METHODS

METHOD is a good servant but a bad master, and it is useful to appraise from time to time the value of all routine procedures This has been attempted for the methods used to control tuberculosis by Dr Jean Downes in the Milbank Memorial Fund *Quarterly Bulletin* for October, 1936 Dr Downes believes that to ascertain the effectiveness of our procedures it is necessary precisely to define the objectives of any procedure and to test accomplishment by comparison with other methods or with controls Ten per cent of 1386 cases referred by practitioners to the clinic were found to have tuberculosis, but among 1437 children surveyed in the schools no definite case of tuberculosis was discovered, and under 2 per cent from among 969 referred by the public health nurse In this country it is only practitioners or school medical officers who refer cases to the local dispensary, the other sources are negligible Considering the work from another angle, Dr Downes notes that 2 per cent of 265 examined because of contact with an infectious case were found to be tuberculous, 14 per cent of 266 seen because of suggestive symptoms—cough, lassitude, or wasting—were tuberculous, but no cases were found among 177 persons seen because of other complaints, such as back ache, indigestion, or giddiness Most instances of infection were found during the investigation of families including a primary focus of infection, next came the results from families where tuberculous meningitis had occurred, no cases were found by the investigation of families in which a child gave a positive tuberculin reaction To test the value of the increasingly efficient control two series of families were considered, one group of 51 families coming under observation from 1923–30, a later group of 41 families first seen from 1931–35 Of those from 0–19 years tested with tuberculin 74 2 of the earlier group showed infection, but only 51 6 of the later, 70 per cent of the patients of the earlier group had sanatorium treatment as against 80 per cent of those seen more recently Moreover, 44 per cent of the first group were admitted to institutions within a month and 76 per cent of the second. Contact examination has also become more comprehensive 33 per cent examined as against 51 per cent This short paper introduces no new therapeutic methods, nor does it suggest new modes of control, but it does suggest to all of us the advisability of adopting from time to time a similar survey

INDICATIONS FOR OPERATION IN PYLORIC STENOSIS OF INFANTS

THE introduction of eumydrin as an antispasmodic drug may alter the whole outlook of pædiatricians on operation for hypertrophic pyloric stenosis Meanwhile, however, some observations by Paschlau [1] may be of value His opinion is that the results would be better than they are in many centres if the indications for operation were more exact, and he recommends preliminary X ray examination after a barium meal The child is given a small feed to which a teaspoonful of barium emulsion has been added and the stomach is examined immediately after the feed and again at four and eight hours' intervals Paschlau says that if both the four and eight hour examinations show that none of the opaque meal has entered the bowel this is an absolute indication for operation More usually the stomach has emptied a little, but if after eight hours less than half its contents seem to be in the bowel, then operation is probably the treatment of choice In another group there appears to be relatively good emptying during the first four hours, but almost no further progress in the next four hours This, according to Paschlau, means atony of the stomach, and for such cases operation is also strongly recommended These are the main indications to be gained from the study of the opaque meal. The degree of peristalsis as shown by careful screen examination is said to have prognostic significance, strong peristaltic movements are held to be a good point Paschlau's other observations on the general state of the child cover ground familiar to British pædiatricians and he is also expressing an opinion current in this country when he writes of the risk of making the infant's condition worse by washing out the stomach with an alkaline solution Saline only should be used for this purpose He claims that by a careful study of the indications for operation the mortality rate from pyloric obstruction in two children's hospitals in Berlin has been reduced to just under 4 per cent

PERFORATED GASTRIC ULCER

AT a recent discussion in Brussels on the treatment of perforated gastric ulcer, Dr Robert Leclercq described [1] a case that came under his care at the Hôpital Saint Pierre in which a large perforated ulcer, situated on the lesser curvature, was so rigid and friable that all attempts at suture failed Primary gastrectomy was considered to be out of the question as the perforation had taken place twenty hours before operation Leclercq decided to close the hole by insertion of a hollow sound The manœuvre was successful. The sound used was a soft Nélaton of number 16 gauge, which was kept closed except for a short time in the morning and evening when it was used to evacuate the gastric contents The amounts of fluid obtained from the stomach on five successive days directly following operation were (in c cm) 600, 600, 500, 800, and 1200 On the sixth day the sound was definitely closed, and on the tenth day it was withdrawn A gastric fistula did not form and the wound rapidly healed Three months later the patient was readmitted to hospital Although his general condition was good he still had symptoms and the radiological examination showed considerable deformity of the stomach. A partial gastrectomy was successfully performed

The main points raised in discussing Leclercq's case were the certainty with which perforation of the stomach could be diagnosed, and the indications for and against primary gastrectomy in acute perforation Dr Leclercq was criticised by Dr Appelmans because he had made his first incision over the appendix to rule out the possibility of appendicitis Dr Appelmans said that a simple radiogram would have shown the presence or absence of air under the diaphragm If air were present, operation was urgent and the diagnosis of perforation was proved. The absence of air did not rule out the possibility of perforation, but it did mean that immediate operation was not called for, as the perforation was closed off Dr Demuylder considered that a small diagnostic incision over the appendix was permissible as it could be used, in case of perforation, for the insertion of a suprapubic drain. Dr Leclercq justified his hesitation in diagnosis by the fact that tenderness was most marked over the appendix area and that the gas bubble demonstrated in the X ray was so small that he thought it might have been caused by perforation of a gangrenous appendix. Curiously enough, Leclercq seems to have been surprised to find the stomach full although the retention of the stomach contents is one of the well established facts in cases of perforation. Dr Loute said that his practice amongst the miners in the region of Charleroi had given him an extensive experience of perforation in patients coming to hospital in poor physical condition He considered that the procedure described by Dr Leclercq was a good one and he had himself employed it He was more and more impressed with the number of cases permanently cured by simple suture Dr Appelmans spoke strongly in favour of partial gastrectomy as the operation of choice for perforation wherever the condition of the patient justified it Dr Leclercq thought that too much weight ought not to be given to the statistics which showed greater success with gastrectomy than with suture All the critically ill patients were treated by suture partial gastrectomy being reserved for specially good risks

CHRONIC RHEUMATIC DISEASES

We welcomed the first report of the British Committee on Chronic Rheumatic Diseases above all for its attempt to rouse more professional interest in chronic arthritis and to feed that interest with such grains of wheat as can be winnowed from the chaff of a difficult field The feeding process is continued in the second annual volume[1] and the winnowing is careful. Prof. L S P Davidson and Dr Goldie open it by presenting a reasoned case for regarding all rheumatoid arthritis as chronic infective arthritis Their evidence is circumstantial—such points as the more frequent occurrence of antecedent infections and of infected foci in rheumatoid arthritic patients than in controls and the more frequent findings of streptococcal antibodies in their blood—but it leads them to regard infection along with sensitisation and some constitutional predisposition as the three factors together responsible for the disease Dr W S C Copeman presents a dozen cases of his own and quotes another dozen from the literature in support of the thesis that some cases of rheumatoid arthritis may be tuberculous in origin in 11 of his 12 cases Prof Loewenstein of Vienna found tubercle bacilli in blood cultures A most interesting and valuable chapter is a review of recent American researches on diseases of joints and related structures written by Dr Philip Hench of the Mayo Clinic secretary of the American Committee for the Control of Rheumatism it is a concise and critical survey of the last three or four years for which workers in this country should be most grateful. There are half a dozen shorter papers in the volume including a preliminary report by Dr E G L Bywaters of his researches in Prof Dodds's laboratory into the metabolism of joint cartilage and synovial membrane and an account of an attempt by Dr Philip Ellman and Dr Sydney Mitchell to assess the psychological features of 40 cases of rheumatoid arthritis and 40 osteo arthritics

No cure for rheumatoid arthritis will ever come out of a committee room Dr Hench says but the efforts of an aggressive committee may well provide the future discoverer of a cure with the inspiration and assistance necessary to achieve his success In that hope we trust the efforts of the British Committee will be continued and extended.

RADIUM FROM CANADA

The isolation of radium from the streak of silver radium ore near the Great Bear Lake in Canada has been progressing rather rapidly From an official statement recently issued by the Eldorado Gold Mines Limited who mine carry and refine the pitchblende it seems that unusual problems were posed by the unparalleled richness of the ore in radium The technical side of production has now been solved by the Department of Mines with the assistance of Mr L Pochon who had worked at the Curie laboratories in Paris By October 1936 the production of radium had reached two grammes monthly and the first ounce was completed on Nov 16th The capacity of the refinery is expected shortly to be trebled and orders to the value of more than £800 000 are to be met in the coming year It is stated that the market price of radium has been halved as a result of developments in Canada and there is welcome assurance that with increasing success there is no intention of raising the Canadian price to an exorbitant level.

THE BLOOD IN HODGKIN'S DISEASE

Hæmatologists do not agree about the peripheral blood picture in Hodgkin's disease, and it is useful to have Wiseman's account[1] of his findings in 31 cases which had not yet been treated by irradiation and in which the diagnosis was confirmed histologically About half the patients he says had a normal total white cell count and the number did not exceed 10 000 per c mm unless the illness was in an advanced stage—all but one of this group having much enlarged abdominal or mediastinal glands The other cases showed a slightly subnormal count, and *there was a definite tendency to neutrophilia.* Eosinophilia was sometimes found and Wiseman suggests that it is constant enough to be an aid to diagnosis though it seemed to bear no relation to the activity of the disease Approximately nine tenths of the patients had an absolute lymphocyte count below 1500 per c.mm (i e a lymphopenia) and in none did the number of lymphocytes exceed the normal. On the other hand nearly two thirds had absolute monocyte counts above 700 All cases sooner or later developed a deficiency both of red cells and of hæmoglobin associated with an increase of reticulocytes Wiseman concludes that a blood picture showing a lymphopenia with a high ratio of monocytes to lymphocytes a neutrophilia and normal total white count should suggest a diagnosis of Hodgkin's disease This cellular response he believes indicates a non pyogenic infectious agent as the cause of the disease and he regards it perhaps rather dogmatically as evidence against either a tumour process or a virus The pronounced lymphopenia in his opinion negatives lymphoid hyperplasia and he considers that the primitive reticulum cell and monocyte are primarily affected. But his suggestion of an infectious agent of low virulence and non pyogenic origin, allied on the one hand to the tubercle bacillus and on the other hand to monocytic leukæmia *is not altogether easy to follow* Finally

Wiseman emphasises the importance of controlling all irradiation therapy by frequent blood counts It is essential that irradiation should be withheld, whatever the clinical condition of the patient, if the total red cell count and white cell count show rapid deterioration

SEQUELS TO CHILDBIRTH

In our first issue of the New Year Dr Méave Kenny described the state of 100 women who had been treated for puerperal sepsis at the Queen Charlotte's Maternity Hospital isolation block at Hammersmith Examining them four or five years after their illness she found that no less than 87 were free from any gross lesion of the pelvic organs, such as tubal masses, uterine displacements, or vaginitis Cervicitis was noted in 5 patients only, and a tubo-ovarian mass in 2, both of whom had previously suffered from pelvic peritonitis The pelvic findings were indeed so far negative that as the investigation proceeded its interest narrowed upon what was emerging as the most appreciable residuum of the original puerperal infection—namely, sterility Among the 100 women during four to five years of the active child bearing period there had been only 5 pregnancies No contraceptive measures had been used by 26 women, and of the 69 who attempted contraception, only 22 employed methods likely to influence the coming of another pregnancy

We recall these findings of Dr Kenny's in order that they may be compared with those recorded in another illuminating article entitled Some Gynæcological Sequelæ of Natural Delivery[1] Here the author, Dr Wilfred Shaw, states specifically that he is dealing with natural confinements, not those complicated by puerperal infection, and the basis of his paper is menstrual irregularities, vaginal discharges, and uterine displacements With great fairness he assesses the importance of these annoying, if not serious, disturbances, and the treatment he outlines is both practical and clear What is most remarkable in looking at the two papers is that a woman seems less likely to suffer from gynæcological sequelæ after a severe bout of puerperal sepsis than if her delivery and puerperium are uncomplicated That this may sometimes be true is suggested by Dr Kenny's observations The patient with puerperal infection has a long period of enforced rest and good food, whereas the woman who has a "natural delivery" is soon sent home to added cares and restrictions

HISTOLOGY OF THE DISORDERED BRAIN

Histological methods of psychiatric research have not been much employed or esteemed in England since sanguine notions about the anatomy of the biogenic psychoses raised hopes that were not fulfilled This neglect of morbid anatomy, now fortunately being made good, did not obtain elsewhere, as may be recognised from the monograph recently published by Schaffer and Miskolczy from Hungary[2] Schaffer's views on the common structural features of the heredo degenerative diseases of the central nervous system have been energetically put forward for a decade, and began with his valuable earlier study of amaurotic familial idiocy In spite of the strong objections offered by Spielmeyer and others to his assertion that exogenous affections can be differentiated histologically from endogenous ones, he has not flagged and now offers a further exposition of his findings An elective and exclusive change in the ganglion cells is for him the criterion of a hereditary cerebral anomaly, with its substrate in the neuro ectodermal hyaloplasm In detailed reports on schizophrenia, senile dementia, and Pick's and Alzheimer's diseases, his pupil Miskolczy gives a well documented review of the data that confirm Schaffer's view What he says of his own observations on schizophrenia is not open to the usual criticism that only the brains of long standing cases with late secondary changes have been examined, on the contrary, he was able to enjoy the gloomy (but, for histologists, enviable) fruits of an apparently high death rate among acute schizophrenics within a few months after their admission to hospital But he is unconvincing in his efforts to rebut the accepted view that the cellular loss in the cortex is an outcome of varied processes, and not itself the primary histological change The technical discussion of the plaques and other features of senile or presenile dementia which he describes is related to schizophrenia by a final survey of the alleged evidence for a hereditary connexion between senile dementia and dementia præcox, Dr Miskolczy decides against such a connexion.

A VERSATILE SCHOOL

Meeting on Tuesday last to receive the latest annual report, the governors of the London School of Hygiene and Tropical Medicine found good reason to be pleased Within a dozen years of its establishment the school has attained a vital position in the medical life of this country, and wields great influence outside England and outside Europe It is a post graduate centre for hygiene and tropical medicine, it sets itself to give helpful answers to the innumerable questions that come from investigators, would be investigators, administrators, and practitioners all over the world, and it ranks high among our institutes of research The dean's report tells of inquiries of so many kinds that the year's total would seem respectable for a small country rather than a single school Mostly their subjects are of more immediate importance to the expert than to the profession as a whole—though it is of interest to know, for example, that Mr A E Oxford has isolated a derivative of tyramine (ergot) "which may be of very considerable pharmacological importance", that Dr Lucy Wills has shown that the hæmopoietic factor in Marmite is not identical with any of the constituents of the vitamin B complex (except possibly B_1) that Dr G P Crowden's use of reflecting surfaces to secure comfort in the tropics now extends to the provision of face masks for furnace workers and sheets lined with aluminium foil to prevent the chilling of accident victims, and that Dr Marion Watson has discovered a diet that produces a definite increase in the resistance of mice to infection by *Bacterium aertrycke* But of all the work described the most striking is certainly the joint researches of the divisions of bacteriology and biochemistry on the isolation of immunologically active chemical substances We hope to be able to publish some of this work in the near future

---

We regret to learn of the death on Jan 18th, at Bembridge, Isle of Wight, of Dr Harold Waterlow Wiltshire, consulting physician to King's College Hospital, at the age of 58

---

PRINCIPLES OF MEDICAL STATISTICS

IV.—THE VARIABILITY OF OBSERVATIONS

WHEN a series of observations has been tabulated—i.e. put in the form of a frequency distribution—the next step is the calculation from the series of certain values which may be used as descriptions of it and enable comparisons to be made between one frequency distribution and another. The value most commonly employed is the *mean* or arithmetic average, and frequently the worker's analysis comes to an end with this calculation. But taken alone the mean is of very limited value for it can give no information regarding the variability with which the observations are *scattered around itself* and that variability (or lack of variability) is an important characteristic of the frequency distribution. As an example Table II shows the frequency distributions of age at death from two causes of death amongst women. The mean or average age at death does *not* differ greatly between the two, being 37·2 years for deaths registered as due to diseases of the Fallopian tube and 36·2 years for those attributed to abortion. But both the table and the diagram based upon it (Fig. 5) show that the difference in the variability or scatter of the observations round their respective means is very considerable. With diseases of the Fallopian tube the deaths in the year's records are spread over the age-groups 0–5 to 70–75 while deaths from abortion range only between 20–25 and 45–50. As a further description of the frequency distribution we clearly need a measure of its degree of variability round the average. A measure commonly employed in medical (and other) papers is the *range* as quoted above—i.e. the distance between the smallest and greatest observations.

TABLE II

Frequency distribution of deaths of women in England and Wales 1934 from (1) diseases of the Fallopian tube and (2) abortion not returned as septic according to age.

Age in years	Diseases of the Fallopian tube.	Abortion not returned as septic
0–	1	—
5–	—	—
10–	1	—
15–	7	—
20–	12	6
25–	35	21
30–	42	22
35–	33	19
40–	24	6
45–	27	5
50–	10	—
55–	6	—
60–	5	—
65–	1	—
70–75		—
Total	206	79

Though this measure is often of considerable interest it is not very satisfactory as a description of the general variability since it is based upon only the two extreme observations and ignores the distribution of all the observations within those limits—e.g. the remainder may be evenly spread out over the distance between the mean and the outlying values or be bunched very closely round the mean, leaving the outlying values as very rare events. In publishing observations it is certainly insufficient to give only the mean and the range; as previously pointed out the frequency distribution itself should be given—even if no further calculations are made from it.

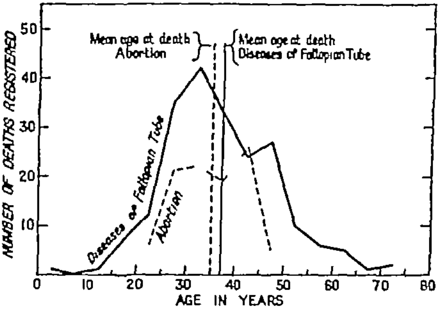

FIG. 5.—Frequency distribution of deaths of women in England and Wales, 1934 from (a) diseases of the Fallopian tube and (b) abortion not returned as septic.

STANDARD DEVIATION

The further calculation that the statistician invariably makes is of the Standard Deviation which is a measure of the scatter of the observations around their mean. Put very briefly the development of this particular measure is as follows. Suppose we have the following twenty observations of systolic blood pressure made on twenty different persons:—

TABLE III

Twenty observations of systolic blood pressure	Deviation of each observation from the mean (mean = 128)	Square of each deviation from the mean
(1)	(2)	(3)
98	−30	900
160	+32	1024
136	+ 8	64
128	0	0
130	+ 2	4
114	−14	196
123	− 5	25
134	+ 6	36
128	0	0
107	−21	441
123	− 5	25
125	− 3	9
129	+ 1	1
132	+ 4	16
154	+26	676
115	−13	169
126	− 2	4
132	+ 4	16
136	+ 8	64
130	+ 2	4
Sum 2560	0	3674

The mean or average blood pressure is the sum of the observations divided by 20 and equals 128. It is obvious from cursory inspection that the variability of the individual values round the mean is considerable. They range from 98 to 160; on the other hand, a large proportion of the values lie in the narrower range 125–135 (50 per cent. of them). The mean and range are not sufficient to describe the distribution. As a further step we may calculate the amount by which each observation differs, or deviates, from the average as is shown in col. 2. If these differences are added, *taking their sign into account*, the sum must equal nought, for a characteristic of the arithmetic mean, or average, is that the sums of the positive and of the negative deviations of the observations from itself are equal. In this example the sum of the deviations above the mean is +93 and below the mean −93. Two ways of avoiding this difficulty are possible: we may add all the deviations, regardless of their sign, or we may square each deviation so that each becomes positive. If the deviations be added in the example, ignoring their sign, the sum is 186 and the *mean deviation* is, therefore, 186 divided by 20 (the number of observations) or 9.3. This is a valid measure of the variability of the observations around the mean, but it is one which, for reasons involved in the problems of sampling, discussed later, is of less value in general statistical work than the *standard deviation*. To reach the latter the squared deviations are used. Their sum is 3674 so that the mean square deviation is this sum divided by 20 which equals 183.7. The standard deviation is the square root of this value (for having squared the original deviations the reverse step of taking the square root must finally be made) and in this example is, therefore, 13.55.

A large standard deviation shows that the frequency distribution is widely spread out from the mean while a small standard deviation shows that it lies closely concentrated about the mean with little variability between one observation and another. For example, the standard deviation of the widely spread age distribution of deaths attributed to diseases of the Fallopian tube (given in Table II) is 11.3, while of the more concentrated age distribution of deaths attributed to abortion, not returned as septic, it is only 6.8. The frequency distributions themselves clearly show this considerable difference in variability. The standard deviations have the advantage of summarising this difference by measuring the variability of each distribution in a single figure; they also enable us to test, as will be seen subsequently, whether the observed differences between two such means and between two such degrees of variability are more than would be likely to have arisen by chance.

In making a comparison of one standard deviation with another it must, however, be remembered that this criterion of variability is measured in the same units as the original observations. The mean height of a group of school children may be 48 in. and the standard deviation 6 in.; if the observations were recorded in feet instead of in inches, then the mean would be 4 ft. and the standard deviation 0.5 ft. It follows that it is not possible by a comparison of the standard deviations to say, for instance, that weight is a more variable characteristic than height; the two characteristics are not measured in the same units and the selection of these units—e.g., inches or feet, pounds or kilogrammes—must affect the comparison. In fact it is no more helpful to compare these standard deviations than it is to compare the mean height with the mean weight. Further, a standard deviation of 10 round a mean of 40 must indicate a relatively greater degree of scatter than a standard deviation of 10 round a mean of 400, even though the units of measurements are the same.

COEFFICIENT OF VARIATION

To overcome these difficulties of the comparison of the variabilities of frequency distributions measured in different units or with widely differing means, the Coefficient of Variation is utilised. This coefficient is the standard deviation of the distribution expressed as a percentage of the mean of the distribution—i.e., Coefficient of Variation = (Standard Deviation ÷ Mean) × 100. If the standard deviation is 10 round a mean of 40, then the former value is 25 per cent. of the latter; if the standard deviation is 10 and the mean 400, the former value is 2.5 per cent. of the latter. These percentage values are the coefficients of variation. The original unit of measurement is immaterial for this coefficient, since it enters into both the numerator and the denominator of the fraction above. For instance, with a mean height of 48 in. and a standard deviation of 6 in., the coefficient of variation is 6/48 × 100 = 12.5 per cent. If the unit of measurement is a foot instead of an inch, the mean height becomes 4 ft., the standard deviation is 0.5 ft. and the coefficient of variation is 0.5/4 × 100 = 12.5 per cent. again. Similarly the coefficient of variation of the blood pressure of Table III is (13.55/128) × 100 = 10.6.

These measures of variability are just as important characteristics of a series of observations as the measures of position—i.e., the average round which the series is centred. The important step is to 'get out of the habit of thinking in terms of the average, and think in terms of the frequency distribution. Unless and until he [the investigator] does this, his conclusions will always be liable to fallacy. If someone states merely that the average of something is so and so, it should always be the first mental question of the reader: "This is all very well, but what is the frequency distribution likely to be? How much are the observations likely to be scattered round that average? And are they likely to be more scattered in the one direction than the other, or symmetrically round the average?" To raise questions of this kind is at least to enforce the limits of the reader's knowledge, and not only to render him more cautious in drawing conclusions, but possibly also to suggest the need for further work' (G. U. Yule. Industrial Health Research Board, Report No. 28, 1924, p. 10).

EXAMPLES OF VARIABILITY

The practical application of the measures of variability may be illustrated by the figures below which are taken from a valuable statistical study of blood pressure in healthy adult males by P. L. McKinlay and A. B. Walker (*Edinb. med. J.* 1935, 42, 407). In the original the full frequency distributions are set out (see Table below).

The variability of these physiological measurements which is apparently compatible with good health is striking. It leads the authors to conclude that we must hesitate to regard as abnormal any isolated measurements in otherwise apparently fit individuals. Some of the measurements they found are definitely within the limits regarded as pathological and study is necessary to determine whether such large deviations from the "normal" have any unfavourable prognostic significance. It is clear that the mean value alone is a very insecure guide to "normality."

As a further example of the importance of taking note of the variability of observations the incubation period of a disease may be considered If the day of exposure to infection is known for a number of persons we can construct a frequency distribution of the durations of time elapsing between exposure to infection and onset of disease as observed clinically If these durations cover a relatively wide range, say 10–18 days with an average of 13 days it is obvious that observation or isolation of those who have been exposed to infection for the *average* duration would give no high degree of security For security we need to know the proportion of persons who develop the disease on the fourteenth fifteenth &c day after exposure; if these proportions are high—i e the standard deviation of the distribution is relatively large—isolation must be maintained considerably beyond the *average* incubation time In such a case *the importance of* variability is indeed obvious but there is a tendency for workers to overlook the fact that in *any* series of observations the variability large or small is a highly important characteristic

Means Standard Deviations Coefficients of Variation and the Range of Measurement (based on 566 observations)

—	Mean	Standard deviation	Coefficient of variation *	Range.
Age (years)	23·2	4·02	17·31	18– 40
Heart rate (beats per minute)	77·3	12·83	16·60	46–120
Systolic B P (mm)	128·8	13·05	10·13	97–168
Diastolic B P (mm)	9 7	9·30	11·76	40–108
Pulse pressure (mm)	49·1	11·14	22·35	24– 82

In actual practice the calculation of the standard deviation is not usually carried out by the method shown above—i.e by computing the deviation of each observation from the mean and squaring it Shorter methods are available both for ungrouped observations (like the twenty measurements of blood pressure in Table III) and for grouped observations (like those in Table II) These methods are described fully in many text-books—e g., Woods and Russell.

SYMMETRY

Another characteristic of the frequency distribution is *its symmetry or lack of symmetry* With a completely symmetrical distribution the frequency with which observations are recorded at each point on the graph or within certain values below the mean is identical with the frequency of observations at the same point, or within the same values above the mean. With asymmetry the observations are not evenly scattered on either side of the mean but show an excess on one side or within particular values—e g with a mean of 50 observations below the mean may not fall below 20 units from that point the lowest observation recorded being 30 while on the positive side of the mean observations 40 units *above the mean may be observed* values of 90 being recorded The tabulated distribution and still more a graph of it will afford an *indication* of this characteristic.

Summary

As descriptions of the frequency distribution of a series of observations certain values are necessary, the most important of which are usually the mean and standard deviation The mean alone is rarely if ever sufficient In statistical work it is necessary to think in terms of the frequency distribution as a whole taking into account the central position round which it is spread (the mean or average) the variability it displays round that central position (the standard deviation and coefficient of variation), and the symmetry or lack of symmetry with which it is spread *round the central position*

A. B H

---

* These are the figures given in the original. According to the values of the mean and standard deviation the final coefficient of variation is 22·60 Probably the original calculation was based upon the values to a further number of decimal places.

SPECIAL ARTICLES

SOME ASPECTS OF INFANT NUTRITION *

By Cécile Asher M.D., B.Sc Lond D C H

MEDICAL REGISTRAR DUCHESS OF YORK HOSPITAL, MANCHESTER
LATE SENIOR RESIDENT MEDICAL OFFICER TO THE ALDER HEY
CHILDREN'S HOSPITAL, LIVERPOOL

The subject of infant nutrition is a wide one and this article concerns certain aspects only and in particular the type of material with which we deal in Alder Hey our methods of investigation and treatment and the conclusions at which we have arrived as a result of 3½ years minute observation of 4036 infants under one year In order to investigate our material we divided the children of this age into weight groups. Of the deaths in children in these groups 60 per cent occurred in those who were more than 20 per cent below average weight This serves to show what an important part the infant service plays in the work of the hospital, and how necessary is a right understanding of the disorders and nutritional needs of these small patients They require unremitting care and watchfulness on the part of the nursing staff They are apt to change quickly for the worse on the other hand one often observes an almost miraculous change as the result of 24 hours intensive treatment so that it is our practice never to give up hope until an infant is actually dead

Methods of Investigating Faults

If a baby is brought to us with the complaint of any nutritional disturbance—i.e diarrhœa vomiting or failure to gain weight—we invariably approach the problem by assuming that there is (1) something wrong with the feed (2) something wrong with the baby or (3) something wrong with both

THE FEED

We first examine the history carefully noting the type of feed the precise amounts given the addition of sugar and vitamins and the intervals at which they are given The child's reaction to each feed is ascertained—that is to say whether he has gained or not the type and frequency of the stools whether vomiting has occurred or not and if he seems satisfied A careful analysis is then made to see if the feed fulfils the rules laid down for the correct feeding of infants, for it is absolutely essential to have rules The baby who, for any reason, has not the good fortune to be fed by its mother is at a grave disadvantage The finding of a suitable substitute for this perfect food should exercise all our ingenuity It should fulfil the following requirements —

---

* A paper read to the Maternity and Child Welfare section of the Society of Medical Officers of Health on July 4th 1936

(1) The energy value should be adequate—i e , 45–50 calories per lb expected body weight

(2) There must be no harmful bacteria

(3) It must be easily digestible

(4) There must be enough protein, carbohydrate, mineral salts, water and vitamins A, B, C, D

There is enough protein if 1½ oz cow's milk per lb body weight per day is given As at least this amount is required to meet the calorie requirements we need not calculate the protein content separately, and it can be neglected when milk and water mixtures or dried milks are used It will be found to be deficient in many of the patent foods and condensed milks For the carbohydrate there are various rules For normal babies it is safe to give 1 oz sugar a day under 3 months, and 1½ oz a day from 3 months to 6 months Starch may be added after 6 months The volume of feed taken should approximate 2½–3 oz per lb body weight per day

The most usual cause of failure in artificial methods is underfeeding This may be qualitative or quantitative, or both , or qualitative underfeeding may be combined with quantitative overfeeding—i e , the calorie value is too low and the volume too large The baby fails to gain because its stomach is distended The mother thinks the feed is too strong and makes it more dilute, instead of cutting down the amount of water added Other errors are too frequent feeds, and feeds too low in protein and too high in sugar, as in condensed milk

THE BABY

Having noted which symptoms of nutritional disturbance are present—i.e , diarrhœa, vomiting, failure to gain weight—we proceed to look for their cause A careful physical examination is made In the osseous system the size of the fontanelle is measured and the skull palpated for cranio tabes, which we have found to be as common in wasted infants as in rachitic or syphilitic infants A minute examination is then made of the other systems to find infection, if present The nasopharynx, the tongue, the buccal mucosa, and the fauces are examined very carefully The tympanic membranes are inspected by means of an electric auriscope, with specially constructed oval speculum The heart and lungs are auscultated, and the liver, spleen, and glands palpated Any skin lesions are noted The state of the tissues, if there has been recent loss of fluid or of fat—the difference between dehydration and emaciation—is of profound importance in influencing treatment Finally, congenital abnormalities are noted

The following special tests are then carried out intradermal tuberculin injections as a routine , Wassermann reactions where suggested , hæmoglobin, when anæmia is suspected , urine and stools routine examinations and culture , and radiography when indicated Biochemical examinations are performed, such as sugar tolerance curves on wasting infants, estimation of alkali reserve in severe diarrhœa and vomiting, and blood urea when we suspect renal failure Blood calcium and phosphorus are estimated in early rickets and tetany

Types of Nutritional Disturbance

The following classification is in use —

(1) Athrepsia infants more than 40 per cent below average weight for age

(2) Hypothrepsia those who are 20–40 per cent below average weight

(3) Dyspepsia

(4) Fermentative diarrhœa

(5) Infectious diarrhœa

(6) Parenteral diarrhœa

ATHREPSIA AND HYPOTHREPSIA

We have abolished the use of the term marasmus, for we found it was apt to be used loosely to describe any nutritional disturbance, and not merely for children who had wasted Moreover, it was often regarded as a diagnosis in itself Athrepsia and hypothrepsia denote definite degrees of underweight, the former being more or less synonymous with the gruesome term "dekomposition" of the German writers and the "atrophy" of English writers The cause is uncertain There is often a "constitutional" element present, whatever that may mean Congenital abnormalities such as heart disease and syphilis are associated with wasting, and there may be achlorhydria Infection may be a factor, or the child may have been underfed for a long time Whatever is causing the condition, there is a breakdown in tolerance—i.e , in the ability of the child to digest and assimilate its food When such a breakdown has occurred, he should be fed on his basal requirements only, that is, about two thirds of optimum previously outlined No quantity gain (or gain in pounds and ounces) is likely for some time, but quality gain (or freedom from symptoms) is expected This quality gain is the period of repair, and is very real and definite When in spite of his weight line being flat the baby begins to look happy and active with a pink colour, glossy skin, formed stools, and no vomiting, repair has begun and the feed can be gradually increased to optimum requirements, when he should put on weight When a baby is not gaining weight one is tempted to raise the calorie value of the feed He may gain for a day or two but the weight line will become flat for a time and will then drop This is the so called paradoxical reaction to food, which occurs when the feed is raised before tolerance is re established One has only to experience this a few times to realise how very cautiously the infant's feed should be increased when he has not gained for a considerable time and one suspects a breakdown in tolerance

In order to give the underweight infant its optimum requirements a high calorie, low volume feed is needed. One finds it impossible to give enough calories without giving too large a volume if milk and water feeds are prescribed (This refers only to underweight children , milk and water feeds are satisfactory for normal babies) In this hospital we use lactic acid milk, with the addition of as much as 7½ per cent of commercial glucose , it is not pure but consists of a mixture of dextrose, maltose maltodextrin, and dextrin, which is an advantage The energy value of this feed is 30 calories per ounce Lactic acid milk is prepared by the addition of lactic acid (B P) to whole milk, which leads to the neutralisation of a portion of the buffer substances present, so that when the milk is given the degree of acidity attained in the stomach approximates that when human milk is fed Owing to this increased acidity one is able to use undiluted milk, and thus a high calorie feed is available Alternatively, we u

Czerny's butter flour mixture with added milk which has 24 calories to the ounce The mixture is taken well by infants who fail to gain but do not vomit or have loose stools but it should never be used for vomiting babies While these infants are reviving their tolerance subcutaneous salines are given with 5 per cent. glucose in order to maintain the fluid content of the tissues In addition to their feeds vitamins A and D are supplied in the form of Adexolin 3 drops in each feed Orange juice is given daily up to 3 teaspoonfuls Iron in the form of ferric ammonium citrate is given daily in small doses increasing up to 9 grains

If the infant fails to gain and yet has no symptoms of dyspepsia as evidenced by diarrhœa or vomiting we suspect that there is absorption but no assimilation Sometimes gain in weight can be obtained at this juncture by giving insulin or thyroid In the absence of any symptoms pointing to thyroid deficiency or of any definite indications from the sugar tolerance curves our practice is first to try insulin If the baby does not gain or even loses weight we stop its administration and after a few days rest try thyroid Insulin is given half an hour before meals the initial dose is 1 unit the amount being cautiously increased The nurses are instructed to watch for signs of hypoglycæmia and they know what to do should this occur We have an infant in the hospital who has a diabetic curve and who has been having until recently 20 units of insulin daily an enormous dose per pound body weight when compared with adult dosage He has gained steadily since insulin was started, and recent curves show that he has reacquired his tolerance to sugar One finds that the liver enlarges during insulin administration presumably owing to glycogen storage Whether this is deleterious in the long run or not I cannot say Thyroid and insulin are the only endocrines which we have used, but we are hoping to try Eucortone in the near future

There is one more measure that we sometimes adopt in the treatment of athreptic and hypothreptic infants That is blood transfusion The blood is injected slowly into the external jugular vein (never into the longitudinal sinus) We have not been greatly impressed with the results of these transfusions

If the infant fails to improve after all these measures and if he fails to absorb and assimilate his basal requirements he will go downhill and die There are several ways in which this may happen He may lose weight and acquire a terminal diarrhœa This diarrhœa is due to general depression of the function of the body cells and failure to absorb both the fluid administered and the pancreatic and intestinal secretions It is an inanition diarrhœa and infants succumbing in this way should not be said to die of gastro-enteritis It is not an enteritis for there is no inflammatory condition of the bowel It is merely a sign of cessation of function and so of absorption The child may acquire a parenteral infection—nasopharyngitis otitis media or pneumonia which may be accompanied by parenteral diarrhœa. Dehydration intoxication and death end the scene He may die from thrombosis of the venous sinuses This depends on concentration of blood and decrease of blood volume which is associated with states of malnutrition and dehydration The blood tends to stagnate in the sinuses and thrombosis occurs It should stimulate us to be assiduous in giving parenteral fluids while the infant is trying to acquire tolerance again Clinically the child becomes quiet the colour is greyish and there is pyrexia It reminds one of cerebral hæmorrhage seen in the new born infant we have verified several of these cases post mortem Or finally he may develop a terminal uræmia as a result of renal failure This, however is usually secondary to dehydration and intoxication.

DYSPEPSIA

We put early feeding errors such as underfeeding vomiting due to overfeeding—quantitatively qualitatively or both—into the class of dyspepsia It is the early stage of a breakdown in tolerance

FERMENTATIVE DIARRHŒA

Overfeeding with carbohydrate causes fermentative diarrhœa which is seen par excellence in babies fed on condensed milks and other patent foods Many patent foods do not contain enough fat and protein being filled up with excess carbohydrate because of its cheapness As a result of this excess water is held in the tissues and the baby becomes hydrolabile— water baby These infants on high carbohydrate feeds gain weight on account of this bound water They lose weight and go downhill very quickly when they acquire an infection as the water is released from the tissues The stools in this type are acid frothy and frequent The treatment is to give by mouth only sterile water or Ringer's or half-strength saline for 24 hours Then small feeds of protein milk are given; we use calcium caseinate added to skim milk The stools become alkaline there is putrefaction instead of fermentation The intestine is rested and a cure usually results The infant is gradually put on to a suitable feed for discharge

INFECTIOUS DIARRHŒA

By infectious diarrhœa we mean that in which an organism can be isolated from the stool and held responsible for the disease It manifests itself clinically by pyrexia accompanied by the passage of loose and frequent stools which may contain blood and mucus In some cases however blood and mucus are not seen and the disease is not so easy to recognise especially as it may be complicated by or accompany parenteral symptoms

If not seen and treated early it leads to dehydration and intestinal intoxication as does any unchecked diarrhœa In routine examination of infants stool paradysentery bacilli such as the Morgan bacillus are frequently isolated Some of the infants in whose stools these organisms are found show no nutritional disturbance It is difficult to know exactly how much importance to attach to these findings

The *prophylactic* treatment of infectious diarrhœa is of paramount importance All infants under the age of nine months are cot isolated Nurses and doctors wear separate gowns for each infant and wash and disinfect their hands before and after handling them The feeds are prepared by a special staff in the milk room A fierce war on flies is waged by means of fly swatters and fly papers Fly screens are attached to the windows of the baby ward The *curative* treatment is to cut down the food till tolerance is reacquired and to restore body fluid by giving parenteral salines We have tried Morgan vaccines on a few cases but have not found them to be of much benefit

PARENTERAL DIARRHŒA

The diarrhœa that accompanies parenteral infections such as nasopharyngitis otitis media tonsillitis bronchitis and pyelitis we term parenteral diarrhœa If an infant who is on a well constructed feed and is gaining weight and looks well, suddenly starts to vomit or has a loose stool, we immediately look for a focus of infection The mouth, throat, ears, chest, and urine are carefully examined Most often, a lustreless, tympanic membrane is found If left alone and examined again the following day it will probably be injected and bulging slightly If a myringotomy is performed at this stage and pus is obtained, one is often gratified by the immediate cessation of symptoms, followed by gain in weight Such a happy train of events, however, does not always occur In a previously healthy infant the outlook is good, but in the undernourished and debilitated, mastoiditis is a frequent sequel to otitis media

One of the most difficult problems in the treatment of infants is the indications for mastoidectomy In general, if any infant has had a discharging ear for more than two weeks and shows no signs of improving, mastoidectomy should be considered But there is another large group of cases in which there are no localising symptoms, when we can only guess at the presence of pus in the mastoid by the severe toxæmia of the patient This may sound far fetched, but it is true We were recently impressed by the number of cases of diarrhœa and vomiting which came to post-mortem, in which extensive mastoid disease was discovered I do not refer to the presence of mucopus in the antrum, which I am aware is often a terminal event, but to cases in which the mastoids were severely infected, and the disease so extensive that the condition could almost be described as osteomyelitis of the petrous portion of the temporal bone In some of these cases we had suspected ear disease and performed myringotomies In some, however, there had been no changes in the tympanic membranes which suggested the diagnosis At this time we tried to decide which cases of diarrhœa were probably due to mastoid disease Clinically, those in which toxæmia was present, when vomiting was severe, seemed to be most often associated with mastoid disease In order to try to save some of these infants, we performed several mastoidectomies on babies with severe diarrhœa and vomiting but no definite localising symptoms The results were interesting The infants all survived the operation for at least 12 hours Those in whom the disease was extensive died within 24 hours Some were no worse but did not improve In a few pus was not found in the mastoid But there were several cases in which the results justified the procedure, as from the day following the operation they began to gain steadily, lost their diarrhœa, and ceased to vomit The results on the whole are therefore discouraging, probably because the operation is not undertaken early enough I believe that it should be performed far more often The difficulty is to select the right cases

Of the other parenteral infections, pyelitis is more likely to cause vomiting than diarrhœa Any of the other infections including syphilis and tuberculosis, may lead to diarrhœa

Treatment

PARENTERAL INFECTIONS

Myringotomies and mastoidectomies have already been dealt with The rest of the treatment of parenteral infections is mainly prophylactic In order to prevent the children from acquiring infections in hospital we wear masks over the nose and mouth when attending to them. We are much more dangerous to them than are their parents, because we are in repeated contact with organisms to which we acquire a partial immunity To the infants we are thus a source of danger as carriers We do not claim that the masks prevent all possibility of infection passing to the child, but we do think that they serve to remind us not to breathe over him, and we hope that they may dilute the dose of the organisms expired.

Infants who acquire the so called "gastro enteritis" in hospital nearly always suffer from a parenteral infection The sore throat of the nurse or medical officer is reflected in the stools of the infant. Again and again we have proved this to be true When an epidemic of loose stools occurs in a baby ward, our practice is to examine and swab the throats of the nurses on the ward and the medical officer Usually one of them is found to harbour a hæmolytic streptococcus

Since the wearing of masks these epidemics have fortunately been infrequent The fact that they do still occur at times serves to remind us that our masks are not infallible As a further prophylactic measure we instil 2 per cent ephedrine in oil into the nostrils of all infants, thus shrinking the mucous membrane of the nasal passages and promoting better drainage Also, we nurse the babies sitting up in the Fowler position This is because they are at a disadvantage compared with adults in that their Eustachian tubes are short and wide Thus when lying supine, nasopharyngeal secretions flow readily into the middle ear, hence the frequency of otitis media in hospitalised babies

DIARRHŒA AND VOMITING

We have now discussed *fermentative, infectious, and parenteral diarrhœas at some length* Whatever the cause of the diarrhœa, if it has persisted long enough, the end result is the same—severe anhydræmia or, as some prefer to call it, intestinal intoxication The immediate need is to restore body fluids If acidosis is present, alkalis should be given, if alkalosis, chlorides, if ketosis, glucose. We can determine the alkali reserve by Van Slyke's method, and administer fluids accordingly In actual practice, however, we rarely do this We give, instead, Hartmann's solution, which is so constituted that it combats acidosis, alkalosis, and dehydration.

If vomiting is severe we give intravenous glucose in Hartmann's solution If vomiting is *not* severe we rely on subcutaneous 5 per cent glucose in Hartmann's, given eight-hourly to overcome dehydration. Subcutaneous salines are efficient in overcoming dehydration, whereas intravenous glucose is a valuable method of dealing with ketosis Hypertonic injections of glucose intravenously can with advantage be combined with the intraperitoneal injection of Ringer's or normal saline, or Hartmann's solution. The hypertonic glucose draws the weaker solution from the peritoneal cavity into the blood stream, thus serving to dilute the toxins and promote diuresis

In some cases where diarrhœa is severe *and incessant* continuous intravenous fluids are given. A blunt needle is tied into the saphenous vein *Fluid* is allowed to drip in at the rate of 1–2 c cm. per lb body weight per hour

We use no drugs in the treatment of diarrhœa with the exception of kaolin (aluminium silicate) which is said to adsorb toxins and remove them from the stools It is valuable in the early stage of diarrhœa

For children over one who are not needing paren ral fluids we give raw sieved apples four hourly 'e have been favourably impressed with this treatment The children take the apple readily and are ore contented than when they are fed on an entirely uid diet. Apple is filling, and they acquire a omforting sense of repletion

THE DEFICIENCY DISEASES

I do not propose to deal exhaustively with rickets urvy and nutritional anæmia, but to make a few marks on the treatment of rickets Most cases of ckets heal readily with the mercury vapour lamp nd cod liver oil, of which it is important to give nough or healing is long delayed 3000 international nits are needed daily to cure and 1500 units to *revent rickets That is to say 1500 units daily* hould be taken by the end of the first year his amount is contained in 1 5 c.cm Radiostoleum 5 c cm. Adexolin or 3–4½ drachms of cod liver oil epending on the standard used Twice these doses re needed if the child actually has rickets If the od liver oil emulsion is used very much larger doses re necessary As we find the amount of cod liver il required daily is more than a great number of hildren could tolerate we reinforce it in this hospital ith radiostoleum. We add 1 c cm of radiostoleum o 1 oz of cod liver oil By this means the vitamin ontent of the oil is raised so that 2 drachms daily i prophylactic and 4 drachms daily a therapeutic dose.

AFTER CARE

So much for our method of treatment in hospital When an infant is gaining weight on a suitable feed hat is one which fulfils the requirements already aid down it is discharged as cured. The mother is iven precise instructions in the milk room as to he preparation of the food The maternity and hild welfare service is notified of the discharge nd the health visitor visits the child in its ome, and sends a report back to the hospital on the ondition of the infant and on the parents capacity o carry out instructions These reports are extremely aluable The children are referred to clinics and re asked to attend the after care clinic in the hospital t least once so that we can see whether or not they ave progressed since discharge

Conclusion

An attempt has been made to outline the methods of investigation and treatment of the infants at Alder ley I cannot help feeling that the treatment of nfants in hospital is not satisfactory They are more han metabolic problems Apart from the risks they un in catching infections they require a normal ome environment—i e the caresses and attentions of their parents and the presence of brothers and isters

T Brenneman of Chicago says (*Amer J Dis Child* 1930 40 12) —

> The herding of infants in separate wards where the ndividualisation and mothering of the home are wanting where exposure to infection of the respiratory tract leads o more institutional casualties than one can contemplate with serenity of mind and of heart is fraught with such danger that one wonders if it were not better to abolish them altogether In our hospital we have tried to meet the situation both by not admitting the type of case that is still commonly admitted and by discharging others at the earliest possible moment The baby clinic department and the out patient department has thus grown at the expense of the infant ward.

I heartily concur with every word

I should like to finish these remarks with a plea for the encouragement of breast-feeding Breast fed infants rarely fall victims to the maladies outlined in this paper If breast feeding were more universal the baby wards would be emptier and fewer infants would be called upon to brave the dangers of hospitalisation. The breast fed infant rarely succumbs to infection

I am indebted to Dr W E Crosbie for permission to publish this paper and for much helpful criticism.

HOSPITAL PLANNING AND DEVELOPMENT

"*A serious responsibility rests upon all who build* hospitals. They must not forget how long lasting are mistakes which are embodied in steel and concrete A hospital in its every section must be planned for its work There is reason to fear that, even to-day hospitals are being built which do not fully conform to that basic *principle*

This passage appears in an interesting section on hospital planning and development included in Sir Frederick Menzies s latest report on general and special hospitals.[1] The London County Council have determined to standardise the dimensions of certain types of sick ward to be erected in future at the general hospitals under their control—viz single bedded wards and large wards of the type which must still be considered the normal type that is to say those in which the beds are placed on either side of the ward and project at right angles from the side walls' The standards decided upon are as follows :—

Single-bedded Wards

Minimum floor dimensions		11 ft by 10 ft.
Minimum height		10 ft

Large Wards

(*a*) Wall space per bed	Acute wards	8 ft
	Chronic wards	7 ft (8 ft. if often also cases are treated)
	Cot wards	7 ft.
(*b*) Width of wards of all types		26 ft.
(*c*) Height		11 ft. (up to a length of 60 ft) 12 ft. (when the length exceeds 60 ft)

These dimensions afford rather more than 100 sq ft of floor area per bed for the acutely ill and 90 sq ft for chronics The longitudinal and lateral standards are justified not only on grounds of comfort and well being of the patients but also by the convenience of the staff and the efficiency of their work More than once it is emphasised that they have not been reached from theoretical considerations but are based on practical experience and we are reminded that that eminently practical authority Florence Nightingale prescribed them in 1863 although subsequent experts on hospital design have frequently departed from them On the financial side it is mentioned that each additional foot of ward width costs only £1 per bed, but it is hardly a just comparison to place against this figure as the report does a reasonable total cost of £800 per bed for initial hospital construction The latter figure includes all buildings such as staff quarters laundry engine house kitchen &c The real additional expense of added width would be better stated in relation to the estimated average cost per bed of a ward-block only Even then it would represent a relatively small proportion

---

[1] London County Council Annual Report of the Council 1935. Vol IV (Part I) Public Health—General and Special Hospitals. London: P S. King and Son Ltd. 2s 6d.

Most administrators of hospitals will probably agree with standards providing 8 ft bed centres and 26 ft ward-width, although it is doubtful if a modernly furnished and equipped ward need exceed 24 ft While wards intended for infants and young children may quite conveniently be narrower, it is probably wise to provide for the contingency that these wards may come to be used for adults For the same reason, and because the dangers of droplet infection are far greater in children's wards, there may be some doubt as to whether there is justification for reducing the wall space in their case from 8 to 7 ft Window spacing in this type of ward conforms to bed spacing and stereotypes the arrangement of the beds, whether they are used for adults or children The standards of height laid down are also generally accepted in modern hospital construction As Sir Frederick says, variations in height affect building costs to the greatest extent The arguments used in reference to the condition of air in a ward would, however, if applied to the patients' comfort and well-being, hardly support the sweeping and rather dangerous statement that "appearance is the single consideration which should govern the height of wards" This is very nearly true, but not quite

BED ALIGNMENT

It is not clear from the report whether Sir Frederick accepts the view that the type of ward which he describes as "normal" is also the best Probably it has been thought that wards of a design common in other countries, but rarely seen in our general hospitals, are still at too experimental a stage to permit of standardised dimensions If, on the other hand, the L C C propose to adhere to the orthodox British type of ward, the reference, quoted above, to mistakes embodied in the modern structural materials "steel and concrete" may be prophetic Apparently, however, the L C C are themselves prepared to experiment, for a scheme for a large extension of the North Eastern Hospital (for infectious diseases) which was described in a report of the hospitals and medical services committee, dated Oct 18th, 1934, included eight ward blocks each with two wards of 20 beds divided into bays of four beds each by dwarf glazed screens Each of these wards is T shaped with sun verandahs at the ends We understand that the beds in these new wards are arranged parallel to the external walls, except at the angles where the peculiar design renders this impossible

The opening of the new Southend General Hospital in 1932 aroused interest in this type of bed alignment As will be seen from the accompanying photograph (Fig 1) the window spaces have been so arranged that the beds may be set parallel to the wall in pairs the occupants facing one another, and separated by partially glazed screens from the next group Each bed or each pair can be completely screened off from the rest of the ward and the patients have a view from their windows without glare Obviously such a ward can carry rather fewer beds per unit of length, if working space is left between the feet of opposite beds but it is reasonable to suppose that the ward may be made somewhat narrower than usual without causing inconvenience A similar bed arrangement has been adopted in the New Sussex Hospital, Brighton Middlesex Hospital has also wards of this kind for special departments, and apparently has contemplated applying the idea to double width wards, presumably with two rows of beds on each side

FOR AND AGAINST THE NEW STYLE

In the first design of the Birmingham Hospital Centre this modern tendency was followed, but the board after very careful consideration, reverted to the old style The arguments for and against the two systems are briefly as follows In the "normal ward a nurse has an uninterrupted view of the faces and demeanour of every patient Moreover, the maximum concentration of patients is permitted with the minimum travelling distance for the staff and the longest striking distance of droplet infection for patients facing each other It is maintained by some hospital administrators that patients like a full view of all that is going on in the wards Wards of this type, being lighted on both sides, and also often at one end, are bright Their structure is simple, the spaces between windows and beds being uniform On the other hand, the advocates of a different arrangement plead that the complete publicity of the open ward is objectionable to many patients, and that the untoward events which occur openly in such wards are psychologically bad for the other inmates The glare from the windows

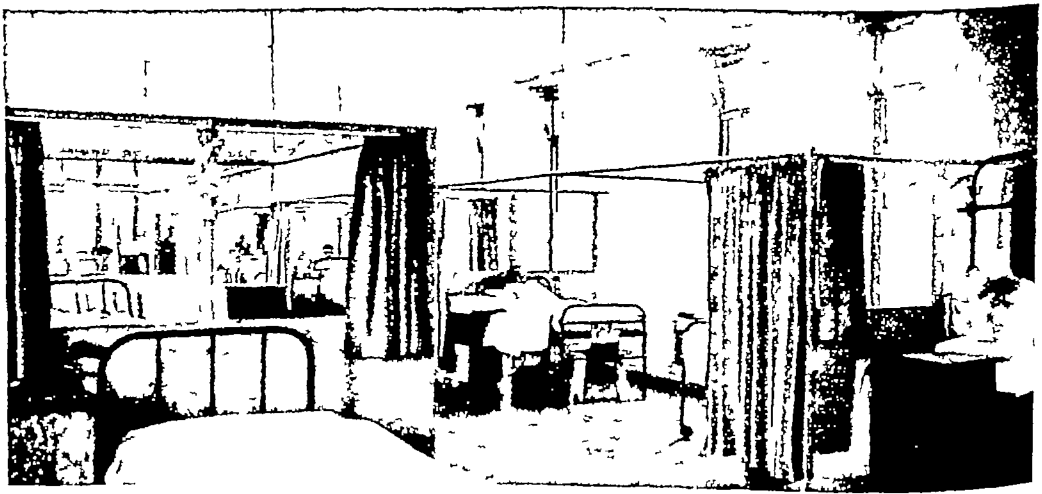

FIG 1 —A medical ward at the Southend General Hospital showing lengthways arrangement of the beds.

on the other side which each patient faces have been proved, they say to cause harmful effects such as headaches Lengthwise arrangement of the beds is claimed to obviate glare and at the same time to afford the patient a view from the window along side of which his bed is set Partitions at the head of each facing pair of beds with in addition curtains suspended from rails round each bed provide an opportunity for varying degrees of privacy which the supporters of the arrangement believe there is plenty of evidence the patients desire Radiators also can be so placed that heat is not most intense at the patients heads where it is least wanted and warmth and ventilation in winter or during excessive summer heat are more easily adjusted It is said that no patient who has been treated in such a ward is happy if he is transferred to one of the old style Critics reply that a nurse has difficulty in supervising the patients whom she cannot readily see that she and other members of the staff have further to walk per bed for each item of service that there is less room for groups of students to surround a bed in teaching hospitals that the desire for privacy is exaggerated and that in any case it is more difficult to secure that privacy at crucial times since in ordinarily planned hospitals the patient would be overlooked from the windows of adjacent blocks.

Dr William Evans who had experience of the new style at Southend and who is definitely in favour of it permits us to use some comments he has made in a private communication As to supervision he is assured by the sister of a medical ward that, after three years experience she would never now desire to revert to the old arrangement When it was suggested that there was need for more accommodation the nurses were anxious that it should not be obtained by conversion to the orthodox arrangement. There is no inconvenience in teaching students since the bed is not contiguous to the wall, as our illustration shows (incidentally it may be said that the number of students who can profit from any sort of bedside teaching at one time is obviously limited) When the patient is screened off he is still in a well lighted compartment comparable to a private room There is less disturbance of sleep at night by the unavoidable activities in other parts of the ward As the patient has at no time more than four patients within view it is easy to protect him from the distress or gloom which results from seeing others who are gravely ill a psychical factor which Dr Evans regards as important In the same category is the outlook on the external world which the patient has from his own window From the surgeon s point of view Sir William Wheeler regards the new arrangement of beds as better for everybody for it makes it possible at any time to convert the space occupied by a patient into a miniature ward whether for detailed examination for recovery from an anæsthetic or for critical illness But he admits that the usual arrangement of beds is more economical of space

The likes and dislikes of patients are difficult to assess Few of them have experience of more than one kind of hospital ward and if they are contented or dissatisfied the cause is just as likely to be temperamental as founded on reason A sociable person who is not too ill may like the bustle of an open ward but the sensitive who may feel most the lack of privacy are probably least likely to open their minds Careful comparisons of the patients reactions under the two systems by such unprejudiced observers as Dr Evans is required to settle this point but we may also ask how we should feel about it if we ourselves were unprivileged patients Long suffering silence is not necessarily evidence of lack of preference Nurses too readily accommodate themselves to conditions and, if they are not temperamentally fault finders are apt to think that system best to which they have become accustomed There would seem to be little advantage in an outlook from a window which is circumscribed by neighbouring blocks or perhaps only their roofs On the other hand the objection to being overlooked by other windows is not insurmountable curtains on windows would be a small extension of the curtains round the beds and are essential to privacy Indeed if the normal healthy person prefers to sleep in a darkened room it is difficult to see why a patient should be wakened by the early summer light in our barrack like hospitals

THE LESSONS OF TUBERCULOSIS

The whole question of hospital situation planning and internal arrangement requires study by the medical and nursing professions There is evidence that architects are eager to experiment with ideas derived from foreign experience Professional caution and perhaps superiority on our part tends to hold them back And yet we have plenty of variety in construction in our own country if we knew where to look for it Since 1912 sanatoria and hospitals for tuberculosis have sprung up like mushroom Their design was originally derived from foreign sources but has been modified to meet the exigencies of our climate Essentially they are built to catch the sun, the patients quarters facing south with small wards, sometimes subdivided in the way we have been discussing, and many single rooms, with wide windows opening on to terraces, balconies, or verandahs, and with well lighted and ventilated passages joining the wards on their north side (see Fig 2) Ready and noiseless means of summoning aid are provided, and, it may be noted, these institutions are not without their emergencies To an increasing extent their patients are the subject of major surgical interference Nearly all the women and most of the men are said to prefer single rooms, when they get accustomed to them Nurses trained in "normal" hospitals readily adapt themselves and find no serious administrative difficulty It is true that their design would be wasted in congested urban sites, for outlook is one of their features, but there are few nowadays who would choose such sites for new hospitals There need be no limit, within the range of structural practicability, to their height, communication by elevator taking the place of the long march from ward to ward which a large, openly spread hospital of the old style entails Those who are planning new hospitals might profitably study the experience of the larger tuberculosis authorities They would find answers to many of their doubts and queries There is much more involved than mere bed alignment

MEDICINE AND THE LAW

Rhabdomancy

EARLIER in the present month the newspapers reported that the services of a water diviner had been employed in the attempt to discover a little girl, aged ten, who was missing from her home at Newark The diviner carried with him a sock worn by the child It was stated that, at one point in his perambulation of the ground, the diviner felt fairly confident there must be something belonging to the girl at that spot

Amid all the controversy between superstition and rationalism, water divining remains a reputable profession in many parts of the country Did not Moses strike the rock with his staff and did not the waters gush forth? If the problem is not so much to indicate the presence of subterranean water as to find it available at a reasonable depth, diviners' rods continue to point to the site of prospective wells and the back breaking labour of well-sinking is undertaken more readily *on that account* The detection however, of buried treasure, missing bodies, and elusive criminals by means of the divining rod is an extension which folklorists can study without the necessity of firm belief Sir George Hill's recent book on "Treasure Trove" mentions the condemnation in Norwich Cathedral in the *fifteenth* century of a woman who brought *a* holly wand (given to her daughter by *a fairy*) to be blessed by the local curate with a view to its being used *for* finding treasure Baring Gould, in his "Curious Myths of the Middle Ages," recounts the career of Jacques Aimar, *a* French diviner who could track down criminals So long as the man practised in the provinces, he was almost infallible, when his fame caused him to be brought to Paris, his gifts deserted him There is a parallel to the recent incident at Newark in the use of the divining rod by a volunteer in the search, not long ago, for the son of a well known artist who was drowned in Cornwall The rod was used on the sea in a boat and was understood to offer indications of the cove where the body should be found. In the United States when the country was stirred by the tragedy of the kidnapped Lindbergh baby, all kinds of magic were placed at the disposal of the police The chief of the New Jersey police force let it be known that, if any two seers agreed upon the same clue, the whole of the police resources would be employed in following up the line indicated. No such coincidence came to his notice, but a medium presented himself who claimed special properties for a small instrument consisting of a lead weight on a rotating arm Some incredulous police troopers were sent with him to pursue whatever course the instrument advised After frequent consultations at cross roads the chase led them confidently to a particular house where the baby would be found. It turned out to be the home of residents of unimpeachable respectability In moments of desperate anxiety it is natural to try any device and to pray for a miracle It certainly borders on the miraculous if a water diviner should possess the qualities of a bloodhound

(FROM OUR OWN CORRESPONDENT)

HEALTH INSURANCE

A PROLONGED and stubborn controversy between the medical profession and the krankenkassen—the health insurance societies—has at last ended satisfactorily for both parties Ever since the upheaval in 1934, when the institutions of the social democratic party—of which the krankenkassen formed an important part—were overthrown, practitioners working under the new "social insurance law" have never known how long they could count upon a livelihood from this source Appointments were only temporary and had to be renewed every three or four months, as the economic situation of the krankenkassen was very unsettled and the financial effect of the new organisation had to be watched before any definite agreement could be drafted One of the chief complaints of the profession was that a fifth of the total income of the krankenkassen—which are united in one large union called the Arbeitsgemeinschaft—was devoted to medical fees and the cost of medicines That meant that the more medicines the doctors prescribed the less money was available for their fees In addition they received each month only a part of their bills, and only at the end of the year the balance would be paid after deducting the costs of medicines and naturally the doctors vehemently objected to this arrangement Now, as has just been reported, the representatives agreed that a quarter of the total takings of the krankenkassen will go to cover the expenses of medical fees and medicines All reasonable remedies will be permitted, so that doctors must have a free choice If a medical man is found to have been too extravagant in prescribing, he will have to refund the excess, or to have his fees reduced by that sum, so that he personally will suffer and not, as hitherto the whole profession A governing committee formed by an equal number of medical men and krankenkassen officials, and presided over by a government delegate, will control the economic questions

The problems involved in this matter are rather important because, as the Minister for Social Welfare pointed out in his recent report, the social insurance law affects about 2 000 000 people 30 per cent of the Austrian population and deals with about £17 000 000 a year in contributions towards sickness benefit old age pensions and unemployment provision In 1935 the Krankenkassen spent 20 per cent. of its income in doctors fees, 0·5 per cent in medicines 15 per cent on hospitalisation 28 per cent for sick pay and 14 5 per cent. for administration A total of 331 000 members are insured against sickness to which must be added 230 000 relatives who are also entitled to reduced fees Further statistics show that besides the total of 2 000 000 persons compulsorily insured against sickness there are 416 000 full time workers and 925 000 half time workers insured against accidents while 210 000 are insured against invalidity 743 000 against unemployment and 871 600 in the old age pension.

COMING MEDICAL CONGRESSES IN VIENNA

This year a number of important medical meetings will be held in the capital The centenary of the Gesellschaft der Aerzte in May will be celebrated by a series of social functions and of lectures delivered by the leading scientists of Central Europe In July the International Congress on Short waves will be held here with d Arsonval and Marconi among its honorary presidents Its transactions will comprise three groups Physics (including chemistry and technical physics) Biology and Medicine In September the customary congress of alpine practitioners (the thirteenth) will be held partly in Salzburg partly in Vienna In addition the preparations for the International Surgical Congress which will take place in Vienna in 1938 are now being made including those for a splendid surgical exhibition The committee of this convention is already very busy with the organisation of this meeting which is expected to be the largest of its kind.

PROF HAJEK S SEVENTY FIFTH BIRTHDAY

A short time ago Prof Marcus Hajek, the rhinolaryngologist, celebrated his seventy fifth birthday Although he had asked that no notice should be taken of the event his friends and pupils and the learned societies availed themselves of the opportunity to pay homage to his splendid qualities. In one of the contributions dealing with his life history it was revealed how Hajek brought up in bitter poverty in the country had to work hard for his living from the age of 14 He soon came to Vienna, where he originally intended to study mathematics and natural history But he was advised to turn to medicine if he wanted to earn his living He did so and as a result became a world famous authority on the nose and throat though his whole career had been paved with obstacles and difficulties When he resigned his office as chief of the nose and throat clinic in Vienna after attaining the age limit of 70 years he turned to his old favourite occupation of mathematics and physics and in the recent celebration said to a friend who was congratulating him: That s all very well but if I had been able to study what I wanted to when a boy I would surely have really achieved something and would not have become a mere laryngologist

ACCIDENTS IN VIENNA

In the annual report for 1935 of the Voluntary First Aid Society some interesting items are worth reading Thus we find that 26 134 persons (about 72 a day) applied for first aid of which about 60 per cent had been injured the rest being due to sudden illness Of the total 14 440 were males, 10 060 females and 1616 children There were 3111 traffic accidents that needed attention 1085 being occupational accidents 725 due to athletics or sports 428 to electric shock or to caustic irritants 618 to alcoholic intoxication and 134 persons were bitten by animals. In 2055 instances suicide was attempted or committed. The society s ambulances were called out over 15 000 times or 41 times a day The expenditure was about £16 000 help being rendered to the public free of charge

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

ABERDEEN AND THE TREATMENT OF RHEUMATISM

LAST November Prof Stanley Davidson laid some of the facts about rheumatism before the Aberdeen Business and Professional Club He told them that a sixth of the industrial invalidity of Great Britain is due to rheumatic diseases and the probable cost to the country is about £20,000 000 a year Rheumatic diseases he said might to day be described as Public Health Enemy No I and action against them was urgently required. Among the measures he recommended were the establishment of special centres for treatment compulsory notification the appointment of a medical staff specially trained for the work and the setting up of organisations in every area to arrange that young adults with damaged hearts should find sheltered occupations As Sir George Newman had said in his report to the Minister of Health in 1928 there is a need not only for diagnostic units but for special arthritis units in charge of full time specialists Prof Davidson suggested that the specialist should be a member of the staff of the medical officer of health and be called assistant medical officer for rheumatism the post being similar to that established for tuberculosis Nothing however had yet been done by the Ministry of Health to carry out these recommendations—made in 1928—and he proposed that Aberdeen should take the lead in Scotland in carrying them out A special opportunity was provided by the fact that Aberdeen was on the point of having a large hospital more or less empty and not required for any other than a medical purpose When the patients were removed from Woolmanhill to the new infirmary at Forresterhill ample accommodation would be available and the cost of reconstruction would be low The fall by 50 per cent in the incidence of tuberculosis in the last twenty five years should have released money that might be used to finance the rheumatic campaign with little or no additional expense to the public health service

Prof Davidson s suggestions received support at a meeting of the Aberdeen and district branch of the British Medical Association on Dec 18th when the meeting was addressed by Dr W S C Copeman physician to the British Red Cross Clinic for Rheumatism London Dr Copeman spoke of the economic importance of rheumatism to the country the financial difficulty found by many approved societies in assisting the rheumatic patient and the fact that societies able to make such provision often did not know where to send patients for treatment He emphasised the need for concentrating on industrial areas and outlined the essentials for an effective centre illustrating by lantern slides the equipment and methods used in the British Red Cross Clinic in London The aim was to allow the patients to continue with their daily work as far as possible, one of the most important points in the treatment of patients of the working class

Among subsequent speakers who supported the establishment of a centre in Aberdeen were the chairman (Dr George Mitchell of Insch), Prof David Campbell of the chair of materia medica in the University, and Dr Thomas Fraser It is to be hoped that this excellent proposal will be carried into effect

GLASGOW CORPORATION AND THE VOLUNTARY HOSPITALS

At a meeting of the Glasgow corporation on Jan 7th it was decided that a subcommittee should be appointed to consider the taking over by the corporation of the voluntary hospitals in Glasgow, and their administration as corporation institutions The decision was approved by 50 votes to 39—2 members declining to vote Speaking against the proposal, members of the Progressive party pointed out that the Government are at present considering the report prepared by the Committee on Scottish Health Services so that this local action is redundant and would be a sheer waste of time It was also pointed out that the health committee has already in hand more work than at any time in the past twenty five years Others deprecated the burdening of the rates with expenses which at present were being met by voluntary subscriptions Mr A Whyte (Independent Labour Party), who submitted the motion, said he hoped the subcommittee would decide that the corporation should control the hospital services in the city and that the Government should accept the financial responsibility Criticising methods at present adopted to raise money for hospitals he asked, "Why should people have to beg for money to bring relief to those who suffer?" and described waiting lists as a crime Mr T A O'Hara (Socialist), convener of the health committee, said there were agreed as to the valuable work done by the voluntary hospitals in the past, but he thought it desirable that a hospital system should be developed which would get rid of the long waiting lists Their inquiry would not prejudice any action which the Government might take, and they might be able to get information that would be of value to the Government

GRAINS AND SCRUPLES

Under this heading appear week by week the unfettered thoughts of doctors in various occupations Each contributor is responsible for the section for a month his name can be seen later in the half yearly index

FROM A PUBLIC HEALTH CLINICIAN

IV

At the vast cosmopolitan caravanserai which sometimes receives me upon my visits to London I sit at the bachelor's table and that brings to my mind the wisdom of June Not the glorious month of which poets write and indeed June is not her name She is just the pleasant, brisk bright little lady that brings my breakfast and I named her June because her predecessor was called May Between courses and mouthfuls, and when the superintendent is not looking we converse and although her vocabulary is more limited than that of Dr Johnson her small head is stuffed as full of wisdom as her large heart is with kindness She has her own views of the guests which have alarmingly little relation to their exalted or humble stations Some of us are repulsive others charming but she classes us all as more or very much less degrees of nice. Lowest grade of all come the really not at all nice next come the not nice, and next the not very nice. More favoured customers may be nice' very nice or at the top of the tree really very nice indeed

A well to do retired bachelor doctor regales us with stories of travels he has made or of travel feasts that he is preparing June comments all very well for him to make us jealous about the good times he has had or means to have *he's only got himself to think about* And on reflection this applies to a number of those who appear fortunate.

An economic crisis and a prosperous business man loses his brisk manner and becomes reserved. Dark rims line his eyes and he eats less breakfast One day he discusses suicide he sympathises with the victims, and says how near he has been himself to that catastrophe It gives June food for thought Oh, these prosperous business men no one hears anything about it when they are piling up money but when anything goes wrong they talk of suicide At this point she whisks away my porridge plate and disappears into the blue soon to return with bacon and eggs and to continue but there I suppose we are the lucky people nowadays we just draw our money at the end of the week and no need to worry about anything

A retired colonel from India tells us wonderful stories about Indian magicians Says June I think he must believe all he's told then later most people believe three quarters of what they are told and not more than a quarter is really true" And the colonel thought we were impressed!

The Lindbergh baby was the topic one breakfast time and June remarked as she brought the fish our police would have found him in a few days these Americans have a lot to say but they're better on paper than in reality With the bacon and kidneys she continued number 252 said last week that America expects that every other nation will do its duty As usual she became mollified as the meal was ending. I wish someone would pay my fare to America I expect they are just as nice as we are when you get to know them. Indeed so do I hope someone will take June to America—not that we want to lose her She will return wiser than ever

It was election time and we were all wondering how to suppress a very opinionated and loquacious diner from the north In an unguarded moment he asked June which way she voted ' I always vote labour said she and vanished. Our friend's jaw dropped and he became silent to us refreshingly silent When he had gone June was confidential Of course I never have voted labour said she they don't know enough about affairs and such like but I thought it might quiet him And it did

Wisdom from divines from hard headed business men and from Members of Parliament is expected but not always forthcoming Give me the wisdom of June.

* * *

The slump is passing and now let us hope the famine in Harley-street will also pass The position is critical there are more plates than ever in the select London spots, and yet a great deal of consulting work has passed to the provinces The London consultant deserves sympathy the small minority are very prosperous some are the reverse and the majority have a hard time with fabulous rents to pay and constant teaching work with free consultations at hospital allows little time for earning It is very unfair but the effects of the famine are far reaching The elaboration and prolongation of diagnosis and the complexities of treatment are not solely the result of scientific progress Students are taught these methods and it is not always to the advantage of the community Questioning an old friend who had achieved a considerable reputation in Harley-street as to his prosperity he replied Oh I am not yet wealthy but thank goodness I can now afford to be honest As far as the speaker was concerned the remark had no substratum of truth let us hope it would not often be strictly accurate; the majority of doctors are ever ready to confess their faults and to join in any merriment at their own expense, but the amusing cynicism may create an unfortunate impression when displayed among the laity

* * *

We hear classical music from ancient and modern composers on the air and at the Queen's Hall, jazz rhythm at untold restaurants and dance saloons, as well as from the B B C The merits of different music are difficult for my generation to assess Souza's band appealed to me, and, when jazz first was played I liked the liveliness of the tunes, which reminded me of the national anthem of Zanzibar Now for so many years we have heard so much jazz that it creates within me unpleasant emotions, whereas classical music arouses more pleasurable emotions, and seems to stimulate thought At different ages the effect may vary, for young people assure me that the rhythm of jazz is delightful and suggests the pleasures of dancing, to me dancing is a minor erotic pastime, to be indulged in only as convention demands, and jazz, therefore, has no appeal It certainly seems that a taste for what is called good music is more often acquired than inborn Perhaps coming years will provide us with a new type of music, or new tunes, or in another 20 years my opinion about such topics will have changed Any individual with a progressive mind may be expected to change his views at least every 10 years

* * *

After discussing music it may be fitting to turn our minds to art A vast subject indeed, and one which appeals to doctors, some of them are artists of merit, while many sketch in a dilettante way At the Herkomer school in my student days I met many artists and found them original and cheery folk, sometimes moody, always intelligent, and with a fondness for the pleasures of life One of them I chaperoned and assisted to secure suitable subjects at the London Hospital for a composite full page drawing in an illustrated paper, which would indirectly assist our quinquennial appeal In the same artist's studio were numerous pictures in colour or black and white, one of which represented an accident to boats during Cambridge May week The artist told me he had been congratulated on the number of lifelike portraits of Cambridge celebrities, "and yet," he said, "they are all drawn from two models" He showed me the similarity of the faces, and with the clues thus provided I have noticed that the same method is generally used by artists, sometimes the model posing as a man, sometimes as a woman. No doubt this fact is already known to most readers but it was new to me

Modern trends in art are, to the simple layman, bewildering It was interesting to be taken round the Royal Academy by an artist and made to realise the value of broad and distant impressions in landscape painting and to be informed that the heavy square, naked forms depicted in some studies showed strength rather than ugliness, which had been my unfettered opinion In spite of all information I still regard those forms as ugly, though ready to believe that strength was what the artist intended to convey, therein lies the insuperable difficulty of most modern artistic trends including abstract art and surrealism. The writer of a letter, review, or journalistic paragraph may fail to convey his exact meaning to the reader although the whole English vocabulary is at his command, the painter of a picture is in a truly impossible position when seeking to convey ideas or conceptions through the vision of various forms or appearances painted on canvas It seems certain to me that the majority of intelligent observers would form widely different conceptions of what is intended. Should we, therefore, taboo these modern strivings to represent on canvas thought or emotions, conscious or subconscious ? Certainly not This new art is an advance which may fail to day and yet have a great future when the artists' powers of expression and the world's knowledge of psychology have both advanced.

CORRESPONDENCE

URETHRAL RUPTURE WITHOUT EXTRAVASATION

To the Editor of THE LANCET

SIR,—It is not perhaps generally recognised that intrapelvic laceration of the urethra may give rise to retention and not extravasation of urine We have recently had experience of two cases in one of which there was retention without extravasation for as long as 29 hours after the urethral injury, while in the other retention was present for 12½ hours It is important to recognise this protective power of the sphincter to hold up urine within the bladder and prevent its extravasation because the surgeon who is unfamiliar with the fact may be tempted into a hurried operation on a badly shocked patient in the belief that he is thereby guarding his patient from imminent extravasation The patient with this type of urethral rupture is typically a youth who has been run over and sustained a fracture of the pubic arch with complete laceration of the urethra and severance of the puboprostatic ligaments At operation the bladder in both of our cases was the size of a coconut It should be mentioned that the delay of nearly 30 hours was not deliberate on our part for this period elapsed between the time of the accident and the boy's admission to hospital. We are impressed with this further example of a natural protective mechanism Both cases have done well after operative treatment

We are, Sir, yours faithfully,

LAMBERT ROGERS,
A L D'ABREU

Surgical Unit Royal Infirmary Cardiff Jan 13th

HOSPITAL AMALGAMATION IN LIVERPOOL

To the Editor of THE LANCET

SIR,—In reply to Mr Bedwell's letter in your issue of Jan 2nd (p 51) the Liverpool United Hospital Bill was deposited at the Private Bill office on Nov 27th, 1936, and Mr Bedwell's quotations from the Bill are taken from the text as printed on that date Subsequent to deposit, however, certain amendments in the text have been made by the promoters of the Bill, and I should be grateful if you would allow me to make certain corrections in those portions of the text which have been quoted They are

(a) "No rule regulation or recommendation of the medical board" now reads "No resolution of the medical board"

(b) "The medical board shall have the supervision of the medical and surgical work of the Hospital and all matters relating to the purchase of surgical instruments and apparatus shall be referred to the medical board that board shall not have power to purchase any instruments or apparatus without the previous sanction of the general committee now reads The medical board shall have the supervision of the medical and surgical work of the Hospital save that all matters relating to the purchase of surgical instruments and apparatus shall be dealt with by the general committee "

(c) The governing body of the Liverpool United Hospital according to the amended Bill will consist of fifty three and not fifty-one members the representation of the Merseyside Hospitals Council having been raised from two to four persons

In addition, Mr Bedwell draws attention to three specific problems The first concerns a provision permitting of the allocation of a percentage of the receipts from the Merseyside Hospitals Council to staff fund ed The amendment suggested to meet this point authorises members of the honorary medical and surgical staffs of the hospital to receive payments under any special arrangements in respect of services provided or rendered by the Hospital to patients students or probationers or to institutions local authorities or other bodies

Secondly [illegible] Mr Bedwell refers to the omission of a reference to the constitution of the Associated Voluntary Hospitals Board. This body which represents the nine teaching hospitals in Liverpool has been empowered by them to make recommendations concerning candidates for posts on the honorary staffs of all Liverpool teaching hospitals and it is hoped that thereby the work of these hospitals may be coordinated to a degree impossible under the system whereby appointments in the past have been made by each individual hospital without relation to other hospitals associated with the same medical school. In [illegible] the opinion of Parliamentary Counsel a close definition of the constitution of the Associated Voluntary Hospitals Board is unnecessary in the United Hospitals Bill.

Thirdly [illegible] Bedwell states that there is no provision [illegible] the representation on the medical board of [illegible]alists other than physicians and surgeons (t[illegible]r with dental surgeons, pathologists and anaes[illegible]ts for whom specific provision is made) This is n[illegible] case In the first instance the medical board of [illegible] United Hospital is to consist by definition [illegible] the holders of all posts set forth in Part I of the annexe to the Bill and the posts there set forth in[illegible]de the obstetricians, gynaecologists radiologists [illegible] other specialists to whom Mr Bedwell refers. All persons subsequently appointed to fill vacancies which occur in the list of posts set forth in Part I of the annexe and all persons appointed to [illegible] all additional offices of a character similar to those held by the persons whose names are set out in Part One of the Annexe will become members of the medical board

I am Sir yours faithfully

A. V J HINDS

Secretary Associated Voluntary Hospitals Board.

Water-street Liverpool Jan. 13th

RADIOGRAM AND RADIOGRAPH

To the Editor of THE LANCET

SIR,—In reading through the supplement to your issue of Jan. [illegible] I note that you state your preference for the word radiogram Personally I have always used during the last 20 years the term *radiograph* in all my writings—a procedure which is in accord with the Shorter Oxford English Dictionary (p 1640) I agree with your [illegible] for uniformity and I am willing to comply; but I should be glad to know why you use the term radiogram which is commonly used for wireless messages and for radiogramophones Surely a photograph and the process used in obtaining such, is so similar that it would seem more reasonable to associate the accepted terms photograph to photograph, photographic and photographer with radiograph to radiograph radiographic and radiographer —I am, Sir yours faithfully

JAMES F BRAILSFORD

Edgbaston Birmingham Jan 5th

To the Editor of THE LANCET

SIR,—In your supplement On Writing for THE LANCET there is one thing and one thing only with which I disagree and that is the use of the words "radiogram and radiograph Whether we like it or not these terms are now wedded for ever to apparatus for the combined reception of broadcasting and the production of gramophone records as well as being also used for telegrams transmitted by wireless I think an effort should be made in medical journals to popularise the use of a skiagram" and if you do not like the verb to X ray why should we not say that the patient was examined by X rays?—I am Sir yours faithfully

London W., Jan. 8th　A MEDICAL JOURNALIST

*** Our preference for *radiogram* is based on the analogy of *telegraph* and *telegram* *Telegraph* dates from the eighteenth century but it was not until the 1850 s that the need was felt for something simpler than *telegraphic message* and *telegram* was devised to signify what was written by the telegraph The Oxford Dictionary points out that the great bulk of the words ending in *-graph* is composed of technical terms of very recent invention mostly expressing the general sense of that which writes portrays or records In medicine as elsewhere *there are various examples of -graph in the agent* sense which have been complemented by *gram* in the passive or resultant sense (e g *electrocardiograph electrocardiogram*). *Photograph* which Dr Brailsford quotes as precedent is really an unlucky exception to a convenient rule: *the public for some reason* never took to *photogram*—perhaps because there was no chance of confusing *photograph* with *camera* The earliest reference we can find to *radiogram* is in April 1896 and not long afterwards alas we were queering our own pitch by using *radiograph* for the picture rather than the machine that makes it *Radiogram* as meaning a wireless telegram was current in 1905 and at that time the wireless experts also claimed *radiography* as their own The medical profession seems to have regained *radiography* and it might still regain *radiogram* As "A Medical Journalist" *says there is nothing* much against *skiagram* except that *skiascopy* (which would be the equivalent of *radioscopy*) already means the determination of the refracting action of the eye We mentioned the skiagram of a sireniform monster in April 1896 and are *prepared if need be* to do so again But if the medical profession in this country is really to retire in disorder before the advancing host of gramophone cum radio manufacturers would it not be best to join forces with our American colleagues and take our stand on *roentgenograph* and *roentgenogram*—words whose *possession no one is likely to dispute?*—ED L.

NASAL SINUSITIS IN CHILDHOOD

To the Editor of THE LANCET

SIR,—I have read with interest Mr Asherson's letter in your *last issue* He says that a difficult problem arises in considering the treatment of the chronic cases—and many become so in spite of all types of treatment" It is to be regretted that no mention is made of one of the most useful forms of treatment in such cases—i e , radiotherapy By this I mean treatment with short (wireless) waves and infra red rays, the application of ultra violet rays by means of quartz applicators attached to the Kromayer mercury vapour lamp to the nostrils and the postnasal space, and general ultra violet irradiation to increase the patient's general resisting powers I have described elsewhere (Therapeutic Uses of Infra red Rays, 3rd ed) the technique and rationale of this treatment

The majority of such children suffer from hypovitaminosis , therefore general ultra violet irradiation of itself must be particularly beneficial to them Suffice it to say that many of us have treated a great number of such cases, and the results are rarely disappointing Almost all the patients are relieved if not cured The fact that this form of treatment causes no pain or discomfort from its inception must make it a pleasing alternative to the methods suggested by Mr Asherson —I am, Sir, yours faithfully,

INFORMATION SERVICE FOR RESEARCH WORKERS IN HUMAN GENETICS

To the Editor of THE LANCET

SIR,—My executive committee invites your coöperation in making known the service here announced One activity contemplated in setting up the Clearing House for Human Heredity is the organisation of information service for research workers in the subject The value of such a plan has been demonstrated in the information service already established for workers on drosophila, &c It should be noted that apart from convenience of ascertaining easily centres at which comparable work is going on, the circulation of notice of their work by those engaged in a particular inquiry is a safeguard in dating priority—a point to which it is natural to attach some importance

Workers are requested to address to the Bureau a short paragraph describing the work on which they are engaged. These notices will be multiplied and circulated to all those coöperating In the first instance this bulletin will be issued every twelve months Later supplementary bulletins will be issued more frequently Those using this service are asked to subscribe 5s , a sum equalling approximately one quarter of a pound sterling equivalent in the currency of their country The accepted languages are French, German, English —I am, Sir, yours faithfully,

R RUGGLES GATES
Chairman Bureau of Human Heredity

115, Gower street London, W C 1, Jan. 14th

TUBERCULOUS DISEASE OF THE ABDOMINAL LYMPHATIC GLANDS

To the Editor of THE LANCET

SIR,—May I state my views on this subject from the point of view of a medical superintendent of an institution for non pulmonary tuberculosis ? Almost all the cases that are admitted do extremely well on the usual form of treatment for all kinds of tuberculosis—viz , fresh air, nourishing food, and rest In addition they receive artificial light (carbon arc), the old fashioned ung hydrarg rubbed into the abdomen, fresh tomato juice (one ounce three times a day), and careful regulation of the bowels with liquid paraffin when necessary I am convinced, however that the fresh air, good food, and rest are the main essentials of the treatment The response to treatment is much more rapid than in other forms of non pulmonary tuberculosis Among the which do badly are those which have ha intervention before admission They often indolent operation wound discharging pus very resistant to treatment, while others distressing condition—fæcal fistula We a the type of case that is admitted to a gener with acute symptoms simulating other conditions, and in which the diagnosis is until the operation is performed With th of this type of case I am of the opini place for patients suffering from tub minal lymphatic glands is an open air h that the treatment should be on conser

I most heartily agree with Mr Colt (THE LANCET, Jan 16th, p 125) in th clusion that "Tuberculosis of the tends in the main to natural cure," but statement earlier in the paper that " that when a pre operative diagnosis of has been made the safest treatment My view is that when a pre operative tuberculous mesenteric glands has safest treatment is non surgical in the of cases —I am, Sir, yours faithfully,

DR RENALD FERNAL

We have received the following qu lady named Fernald who is seekin concerning an ancestor

"I am trying to locate my ancest Fernald (Fernall, Fernell, Furnell, possibly, Fernefold or Fernewold), America about 1630 or 31 as 'chiru Piscatagua Colony (Mason's Plantatio mouth, New Hampshire, but for a Maine He was a leader in town aff of the first to sign a grant of Glebe in 1640, and a petition to Boston G 1653 to change the name of the tow berry Bank, to Portsmouth' He clerk and recorder, commissioner, su as 'chirurgeon' He thus was app educated man, but we do not know English home of the family I have him through his profession, but success There is a tradition that Chester or from near Chester and from the English Navy to go to A been through a number of the Harle lished ones) in the British Museum r in the Navy at that time but no A coat of arms of the Fernefold was accepted by some members of or five generations ago as being the family, but I do not believe it ha with us Dr Renald's will, referre his children, has never been found preserved at Concord, New Hampsh Johanna Fernall' Dr Renald pro 'd' because it went well with his f been told that there are records (o and/or first half of the sixteenth that each 'doctor' or 'chirurgeon' had a certificate showing that he chirurgeon's instruments and tha to enter the profession. How t what extent was it enforced, if tr know ? And were there lists kept certificates were issued ? As f Fernald was concerned we only Johanna willed to her son Joh books and instruments that we his chest'"

OBITUARY

VILLIAM HUNTER C.B M.D Edin F.R C.P Lond F.R S E

Villiam Hunter who died of cerebral thrombosis ondon nursing home on Jan 13th was born lantrae on the Ayrshire coast in 1801 the the late Robert Hunter He received his education at Edinburgh University where a brilliant student and was awarded the cholarship and later the first Lucas Walker studentship at Cambridge Abroad he for a time in Leipzig Vienna and Strasbourg demic honours included an M D (gold medal) recently as 1927 the Hon LL D Edin He London in the early nineties and was at iched to the West London and the London ospitals In 1803 he joined the Charing

DR HUNTER

[illegible]

Hospital medical school and in 1003 became physician to the hospital. In 1800 he was R C P Lond and afterwards was an or the diploma of the college and for the al subjects at Cambridge and Glasgow

is long life in London Hunter s medical ere centred in Charing Cross and the ver hospitals of which he eventually ior physician and he was elected a vice Charing Cross He was dean of the ol from 1011 to 1015 and built up the of pathology and bacteriology which present Institute of Pathology It laboratories that he pursued his gun at Cambridge on focal sepsis and the severe anaemias. His interest in and school was deep and continuous ular attendant at council and committee ed a prominent part in stabilising the tion of both hospital and school at a and was largely instrumental in recon enlarging the school part of the cost himself defrayed His interests were however to the laboratory and wards torical and antiquarian leanings which n his writing an appreciative and intriguing book entitled an Historical Account of Charing Cross Hospital and Medical School.

In 1015 during the Great War Hunter went to Serbia with the rank of colonel in charge of the British Sanitary Mission to assist the Serbian authorities in controlling a serious epidemic of typhus an onerous task which he carried out with all his energy and resourcefulness in the face of extreme difficulties The main problem at issue was the eradication of lice which were carriers of the fever and he was responsible for the idea of the destruction of these and other vermin by what became known as the Serbian barrel and the delousing train For his services in Serbia he was awarded the decoration of grand officer of the Order of St Sava After Serbia from 1015 to 1017 he acted as president of the committee for the control of infectious diseases in the Eastern theatres of the war and in this he was associated among others with his old friend the late Sir Andrew Balfour By his personal charm and tact as chairman of that committee he created an atmosphere of harmony which was felt by those who came in contact with this peripatetic group of distinguished scientists But his strenuous labours in the East undermined his health, and after the war he seemed to have lost some of that intense enthusiasm which characterised his early days For his war services he was awarded the C B

Hunter s principal contribution to medicine was his work on the severe anaemias and oral sepsis a comprehensive term which he introduced into the literature He separated pernicious anaemia as an entity from the secondary anaemias and insisted on the importance of oral sepsis in its aetiology and although recent advances in haematology have modified this view by his pioneer researches he threw much light on the clinical and gross pathological aspects of that disease

As a teacher he was in no way stereotyped but was an inspiration to his students to think and observe for themselves and succeeded in infecting them with his own enthusiasm As a man Hunter was a lovable character beloved alike by his colleagues and students Many a time in committee his flair for saying the kind thing bridged over difficulties and frictions where reasoned argument had failed Those who had the privilege of his friendship will always treasure the memory of a very perfit gentil knight The deepest sympathy of all who knew him will go out to his widow

The funeral service took place at St Columbus Church of Scotland and he was buried in the cemetery at East Sheen

J M H M

Prof Ledingham writes: As one who recalls with pleasure an intimate companionship with the late Dr William Hunter during a period in his career when his varied talents were placed at the country s service, may I be allowed a brief note of appreciation? It has been said that the war turned William Hunter the consulting physician into an administrator and expert in practical hygiene and I can readily believe the truth of this In pre war days I knew him as an authority on pernicious anaemia on the symptomatology and natural history of which he had written widely and as an unwearied protagonist of the view that some specific toxin derived in all probability from the product of oral or intestinal sepsis was responsible for the hæmolytic phenomena to which he attached a primary and cardinal importance Hunter was well qualified to propound these views, as during his pathological career he had made an important experimental contribution to our knowledge of blood destruction and its relationship to jaundice by his work on toluylenediamin Even now, though we have learnt to cure or rather to keep in abeyance the condition that Hunter made his life study, its precise pathogenesis still eludes us

"When I joined Hunter and his little band of sanitary advisors in Cairo at the close of 1915, Hunter was already a seasoned traveller in war zones In February, 1915 he had led the British sanitary mission to Serbia, and there he had been busily engaged in the control of typhus till June of that year when he became chairman of the medical advisory committee dispatched by the War Office to the Eastern Mediterranean This was a new Hunter I found who carried his 55 years easily Travel and new interests had served but to accentuate his sprightly and debonair figure Pernicious anæmia was by no means forgotten, but now the Serbian barrel and the travelling railway van disinfector held the field. The former, a device of Lt Col. Stammers had served well in Serbia, and now when Egypt was rapidly filling up with imperial troops in the early months of 1916, the provision of similar measures became an urgent necessity Hunter with his Serbian experience behind him was in his element Well do I remember, at a wayside station in the desert, the first try out of a railway van steam disinfector, packed with tightly rolled kits, and an assortment of bacterial cultures and other test objects embedded in the mass It was clear to most of the audience when the contents of the van were turned out that the pressure steam had done its work well, and at the finish as Hunter stood proud and happy adjusting a Laurens cigarette to his holder, a zealous but rather incredulous medical officer went up to him and in all seriousness asked 'Will it kill a weevil, Sir?' 'A weevil?' said Hunter completely nonplussed but ready to bluff it out, 'A weevil? Has anybody got a weevil?' No one obliged, the crisis passed, and Hunter turned to me and whispered 'Most amazing! What is a weevil anyway?'

"Hunter's genial and kindly address did much to make things easier for the slacker faced with the omniscient Andrew Balfour full of the latest sanitary wrinkles and eager to impart them, and with the precise and inquiring George Buchanan rapidly filling his notebook with incriminating data shortly to be turned into formal reports for the information of the Higher Command Unfortunately Hunter was unable to accompany the rest of us (Balfour, Buchanan, Wenyon, and myself) to Mesopotamia, but on our return to Egypt in 1917 we found him at his post and had the benefit of his counsel in the concluding stages of the committee's work To me Hunter was the physician who had just missed developing into the experimental pathologist His early inclinations, fostered as they were by the scholarships he held and the post graduate studies he had made in Germany and elsewhere, were, he often told me, towards the laboratory life Taken on the occasion of the International Congress of Hygiene held in London in 1891, he appears in a treasured photograph of the officers of the Bacteriological Section over which Sir Joseph Lister presided, this includes its three honorary secretaries, Ruffer Hunter and Sherrington, who also later left the bacteriological fold The great war recalled to Hunter these primal urges, and he rose manfully to the occasion. In post war days our active paths have crossed but once in connexion with the work of the People's League of Health, in whose inquiries and report (1932) on bovine tuberculosis and the milk question he took an active part Ave et vale"

JOHN ALEXANDER MacWILLIAM, M D, LL D Aberd , F R S

THE news of the death on Jan. 13th of Prof. J A MacWilliam, for 41 years occupant of the chair of physiology in Aberdeen University, has been recorded with deep regret He died in an Edinburgh nursing home in his 80th year, having retired from his professorial appointment in 1927 He was a distinguished student of Aberdeen University, where he graduated M B, C M in 1880, and M.D highest honours in 1882 From 1882 to 1886 he was demonstrator of physiology at University College, London. In 1886 he was appointed professor of physiology in Aberdeen University in succession to Prof Stirling, and during the long period while he filled this chair the physiology department in the University was reorganised and considerably extended Prof MacWilliam will be remembered, not only for his lucid teaching and important research work, but also for his personal qualities His powers as a teacher and his example and influence as a man were much appreciated by his students and by the University for which he worked. He received the honorary degree of LL D Aberd. in 1928 and was elected F R S in 1916 His investigations on the physiology of the heart and circulation are well known and were so advanced that it was not until many years after their publication that their full significance was adequately realised. As far back as 1887 he maintained that sudden death during the administration of chloroform is due to ventricular fibrillation

PROF MACWILLIAM

[Photograph by MacNab

We owe to Prof E W H Cruickshank the following tribute "By the death of Prof J A MacWilliam, the University of Aberdeen and the medical sciences have lost a man who by devoted service to his Alma Mater and untiring zeal in scientific investigation had become known to many at home and abroad As a teacher Prof MacWilliam was noted for the clear and lucid manner in which he could present, with but the slightest reference to notes, the most difficult aspects of his subject As a lecturer he had few equals, every lecture was a finished product, excellently arranged, clearly delivered, full of interest and incident Few there were who attended his course in systematic physiology who did not realise that a memorising of facts was of little importance and that clear reasoning a hysiological problems must play a great part in he training of the mind for the practice of medicine 'o know him as professor was to admire but to now him as friend was to discover new and richer epths of character In the quiet of the study one as introduced to a great personality The experience f the years and they were not without their share f sorrow and suffering had produced a wonderful ombination of philosophic insight and critical cientific judgment By his personal qualities lways gracious, never unkindly critical ever sympathetic Prof MacWilliam endeared himself to many enerations of Aberdeen students His charm of nanner his constant kindness and courtesy won for im the affectionate regard of all who knew him ntimately In the world of science his name has n enduring place in many and diverse circles his nemory will long be cherished

ARTHUR HUGH THOMPSON, M D Camb

Dr Hugh Thompson whose death at his home in Iampstead was announced last week was the oungest of eight children of Charles Thompson of reswylfa, Cardiff where he was born in 1860 He as sent to Quaker schools at Weston super Mare nd Grove House Tottenham and then as Whewell cholar entered Trinity College Cambridge where he ook the historical tripos in 1883 He remained for time in Cambridge as a coach giving extension ectures on history in the northern counties and then went to Toynbee Hall as one of the earliest residents under Canon Barnett. The discovery of his interest in medicine led him back to Cambridge and then to the London Hospital from which he qualified in 1801 at the age of 32 years He was receiving room officer and clinical assistant at the hospital, and after a short period of general practice decided to specialise in ophthalmic surgery

DR. HUGH THOMPSON

[Photograph by [illegible]

Starting at Moorfield as clinical assistant, in 1808 he was appointed assistant surgeon to the Western Ophthalmic Hospital becoming surgeon in 1901 and a member of the board of management in 1003 he remained associated with this hospital through the lean years and was largely instrumental in its resuscitation on modern lines His training and equipment fitted him for critical observation rather than surgical technique he wa an excellent ophthalmoscopic observer and more an ophthalmic physician than surgeon In the care of out patients he spared no time or troubl and he was as iduous in following them up hi major literary output being reports of clinical work of this nature. He also held appointments at the Blind School Swiss Cottage and the Royal Sailors Orphan Girls School Fitzjohn s-avenue During the war he was oculist to the Brook War Hospital Early in his career he became joint editor of the *Ophthalmic Review* and for ten years he contributed reviews of ophthalmological literature to the Medical Annual. Of this part of his work it is possible to speak with some knowledge and assurance for he was a contributor to these columns over a period of twenty years and was in fact engaged on a review for THE LANCET on the morning of his death His knowledge of languages his broad outlook on men and manners, his keen interest in every detail of normal or pathological anatomy and his command of simple natural expression made him an ideal contributor About three years ago he had a cerebral hæmorrhage—fortunately on the right side for he did not lose his power of speech and remained mentally alert through several relapses

Dr Thompson married in 1801 Ann Josephine eldest daughter of Columbus Clothier of Street Somerset They had no children of their own He travelled a good deal abroad and was one of the most pleasant holiday companions He was a keen Liberal and supporter of the League of Nations

WILLIAM JENKINS OLIVER, B.M Oxon , M R C P Lond

WE regret to announce the death on Jan 11th in a Newcastle nursing home of Dr William Jenkins Oliver the elder son of Sir Thomas Oliver the well known Newcastle physician The death occurred suddenly from cardiac thrombosis as a sequel to a serious operation from which the patient appeared to be making a good recovery

William Oliver was born in 1880 and was educated at Winchester and Oriel College Oxford He proceeded for his medical studies to the London Hospital and graduated in 1011 as B.M Oxon later taking the diploma of M.R C.P Lond He early decided to specialise in dermatology and was for a time chief assistant in the skin department of the London Hospital under Dr J H Sequeira On the outbreak of war with a commission as captain R A M C he served as skin specialist at the base hospital at Rouen and he remained for a period at Cologne with the Army of Occupation acting as a skin specialist He was popular with both officers and men in the Army for he knew his work thoroughly well and was always sympathetic with his patients and especially with the children On his return to England he held the post of dermatologist at the Victoria Park and the Evelina hospitals for children and acted in a similar capacity at the Prince of Wales General Hospital Tottenham He was never a very strong man—during the war he had undergone an operation for appendicitis at Rouen—and eventually he gave up a good deal of the dermatological practice which he had acquired in London and decided to spend a considerable amount of time on a farm in Norway and Denmark being an accomplished Scandinavian scholar and also a great fisherman He also studied in Oslo and in the Finsen Hospital at Copenhagen. In research work there he made many friends, chief among which was the veteran dermatologist Prof C Rasch He used his knowledge of Norwegian and Danish to translate several Scandinavian books into English which met with a favourable reception in many journals and in these columns Further during his residence at Flekke on the Sunnfjord he every year acted a locum tenens to the local doctor, enabling that practitioner to have a holiday In that pleasant region distances are great and means of communication scanty, and Dr Oliver came to know the conditions of life on the fjords as well as if he had been a farmer or a fisherman himself Many of his patients there will feel the loss of a friend.

MARGARET THACKRAH, M D , M R C P Lond

Margaret Grace Thackrah, who died in London on Jan 10th at the age of 56, was educated at the North London Collegiate School and University College, London, where she took her B.A degree In 1903 she entered the London School of Medicine for Women, qualifying M B , B S Lond in 1909 After holding appointments of house surgeon to the Royal Free Hospital and medical officer to Maltings Farm Sanatorium, she was for a time resident at the C E Z M F Hospital in Quetta In 1914 she obtained the M D Lond in medicine and during the war she was one of the civilian physicians attached to the Military Hospital, Endell street, and medical officer to a T N T filling factory In 1915 she was appointed assistant physician to the South London Hospital for Women, and from 1926 to her death she was senior physician to this hospital After the war Dr Thackrah became specially interested in the treatment of functional nervous disorders and for sixteen years was psychologist to Dr Barnardo's Girls' Village Home She will be remembered by those who knew her well for her wisdom, loyalty, kindness, and understanding

ALEXANDER McC D MONYPENY, M B , B Ch Belf

The death occurred last month under pathetic circumstances of Dr Alexander McC D Monypeny at his residence in Belfast He was only 33, and his decease followed unexpectedly upon a chill which developed into pneumonia

Graduating in 1927 at the University of Belfast, he spent a year in the Royal Victoria Hospital, Belfast, and on the death of his father, who was a well known and much respected practitioner in Belfast, he succeeded to the practice From the first he showed himself to be possessed of no ordinary ability, but to have a natural gift for his chosen work

A personal friend writes "Alec Monypeny had many friends and intimates He attracted one to him by his generous and kindly nature Considering how hard he worked and how few holidays he enjoyed it was remarkable how much he had seen and done He was well read and had a wide knowledge of affairs which made him a delightful companion and a resourceful friend He was tireless in his energy and conspicuous among his patients for his kindly and understanding nature , nothing was too much trouble for him where their welfare was concerned, and rich and poor alike, he held the same high reputation with both He took special pains to keep himself abreast of the progress of medical knowledge, and at the time of his death had already extended his practice to become one of the foremost in the city His memory will remain dear to all who knew him and to those who were privileged to share his friendship"

JAMES ERNEST LONG, M D Brux , M R C S Eng

Dr James Long, who died in December last, led a notable career as a medical missionary Born in 1874, a member of a well known Bath family, he was educated at King Edward's School, Bath, and Trowbridge High School, and started his career in a well known pharmaceutical business Determining to enter the medical profession, he became a student at the Bristol medical school, and took the English double qualifications in 1898, subsequently graduating as M D Brux He held house appointments on both the surgical and medical sides, at the Bristol General Hospital, and was for a time house surgeon at the Torbay Hospital. He then started in private practice at Weston, commencing at the same time his strenuous work as a lay evangelist While attending to his practice he found time for extensive parochial work, and over a long period was an effective speaker at many religious gatherings, urging upon large audiences the responsibilities of the practical Christian life On the outbreak of the war he joined up immediately, and during his service in England and later abroad he continued his double function as doctor and missionary About sixteen years ago he felt a special call to prosecute this work in India. There he travelled up and down the country going into the remotest parts, and while carrying on his religious work rendered medical aid to the Indians, especially in urgent cases, while frequently he replaced the medical officers at hospitals, thus giving them an opportunity of a much needed holiday He journeyed with his car, and a medical van, into many remote parts of the Empire, where the natives may have seen a white man for the first time, and the value of his beneficent energies was universally and warmly recognised, while throughout he paid his own expenses.

On his return from India, obviously broken in health, he continued to devote himself to his Evangelising work in this country and he collapsed and died suddenly at a religious meeting

THOMAS GOODALL NASMYTH, M D , D Sc , F R C P & S Edin , D.L

The announcement is made of the death, after a short illness, at the age of 81, of Dr T G Nasmyth, whose name has been associated for many years with the progressive side of public health in east Scotland Up to the time of his death he was closely connected with the conduct of hospital and public health matters in Edinburgh A native of Fife, he graduated as M.B , C M in 1876, obtaining the degree of D Sc (public health) in 1887 and M.D in 1889 He took the D P H Camb in 1886, and obtained the F R C S Edin in 1910 In 1913 he was elected F R C P Edin After some years spent in general practice, he was appointed M.O H for Fife, Kinross, and Clackmannanshire, a post which he held for 20 years, when he came to Edinburgh, where he found many outlets for his activity He entered the town council in 1921, served for a term as a magistrate, and took a keen interest in the public health services of the city, being at the time of his death chairman of the Royal Maternity and Simpson Memorial hospital, convener of the medical committee of the Deaconess hospital, vice chairman of the Royal Dick Veterinary College and of the Board of the Animal Diseases Research Association He was also a member of various consultative committees of the Scottish Department of Health, a director of the Highland and Agriculture Society of Scotland and of the Scottish National Housing Company while he gave evidence before various committees of the House of Commons on Miners' Eight Hours Day, Miners' Diseases, and Death Certification. He wrote many papers on medical, surgical, and public health questions, and was the author of one book, The Kingdom Its Characteristics and Distinguished Sons" He was a J.P for Fife and a D.L of the City of Edinburgh

As will be gathered from this list of activities Dr Nasmyth was endowed with a fine constitution and inexhaustible activity of both mind and body which combined with his keen business capacity enabled him even in his later years to take an important place in the work of the community and to lead a life full of interest and usefulness up to the end of his 81 years He is survived by Mrs Nasmyth and one daughter

GEORGE PICKLES ALDERSON M B , Ch B Vict

THE death occurred early in January of Dr George Pickles Alderson a well known medical practitioner at Turton where he spent the greater part of his professional life He received his medical education at the University of Liverpool and graduated as M.B Ch B Vict in 1899 He served for a time as house physician at the Royal Infirmary Liverpool before establishing himself in practice at Turton where he became prominent through his professional and public activities He was for twenty years a member of the borough council and chairman of various subcommittees and in 1925 was appointed J.P for the county of Lancashire During the latter part of his life he gave up a good deal of his private practice but he retained several official positions while his medical practice was continued by his son in law Dr James Cumming He was always particularly active on the county magistrates bench where a sound judgment and genial disposition made him a valuable colleague He was very much interested in probation work and in the activities of the Juvenile Court Apart from his medical and public work Dr Alderson was well known for his interest in pigeons was a leading member of the Manchester Flying Club and owned at different times many prize-winning birds

CHARLES JAMES MILLIGAN L.R C P , L.R C S Edin D P.H Belf

THE death took place on Jan 8th at his house in Ligoniel Belfast of Dr Charles Milligan whose connexion with the medical profession in Belfast had lasted for almost half a century He received his medical education at Edinburgh and qualified in 1888 as L.R C.P L R C S and immediately started in practice in Ligoniel He was appointed dispensary doctor of the district 45 years ago gained an extensive connexion and held a high place in the affections of a wide circle which was exemplified when some 20 years ago on his recovery from a serious illness the residents in his own district joined with friends in all parts of Belfast in presenting him with an illuminated address He retired from his private practice on his appointment as medical officer of health under the Belfast and Castlereagh Rural Council, an appointment which was terminated by his superannuation last year

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Reassembly after Christmas Recess

THE House of Commons reassembled on Tuesday, Jan 19th after the Christmas recess

QUESTION TIME

TUESDAY JAN 19TH

Industrial Health Research

Mr WILFRID ROBERTS asked the Home Secretary if any further report had been received from the Industrial Health Research Board with regard to the effects of noise on the health of the worker —Sir JOHN SIMON replied : I am informed by the Medical Research Council that they have not received any further report on the subject from the Industrial Health Research Board but that investigations are still proceeding I understand that great difficulty is being experienced in finding suitable opportunities or methods for detecting and measuring any effects which noise may have on the workers

Miners and Silicosis

Mr JAMES GRIFFITHS asked the Home Secretary the number of applications for certificates of disablement received by the medical board under the Various Industries (Silicosis) Schemes from among coal miners in South Wales in the year ended Dec 31st 1936 ; the number of certificates granted ; the number of applications rejected ; and the number of *applications* and certificates granted to anthracite miners in South Wales in the same period —Mr GEOFFREY LLOYD Under-Secretary Home Office replied The number of applications for certificates of disablement from coal miners in South Wales during the year was 532 Certificates were granted in 208 cases and refused in 253 cases Of the applications 311 were from anthracite miners of whom 18[illegible] were certified and 115 refused

Mr GRIFFITHS asked if the hon. gentleman was not aware that these men who had been refused certificates were all disabled in consequence of having inhaled dust in their occupation He asked if the Government proposed to bring forward a measure to give elementary justice to men who had laid down their lives for their work ?

Mr LLOYD said that the fact that a man was not certified under this procedure did not necessarily prove that he suffered from an occupational form of respiratory disease He might be only suffering *from a form of respiratory* disease which might not be due to his employment

Mr GRIFFITHS asked when the report of the Government Committee appointed two years ago to go into this question could be expected ?

Mr LLOYD said that the Pulmonary Diseases Subcommittee of the Council recently held a meeting and decided that in the first instance it must come to a conclusion about the essential nature of diseases other than silicosis from which miners suffered As a result they had arranged for clinical and radiological tests on the subject

Physical Training in Schools

Mr SEXTON asked the President of the Board of Education whether he would give special consideration to the institution of a short specialised course of physical training for unemployed teachers to enable them to obtain employment as instructors in schools thus assisting in the Board's activities in improving the physical welfare of the pupils and at the same time giving hope to a body of young men and women who had already undergone a course of training in the training colleges —Mr GEOFFREY SHAKESPEARE Parliamentary Secretary to the Board of Education replied There are already a number of courses of varying duration in physical training for teachers who have left the normal training colleges and who may or may not have obtained posts and it is proposed to increase the number of these courses I do not think that the number of teachers who remain long out of employment after leaving the training colleges would be sufficient to justify special courses for them

Physical Condition of Monmouthshire School-children

Mr JOHNSTON asked the President of the Board of Education whether his attention had been called to the physical condition of the children in the boys' school at Blaina Monmouthshire, where the head master had reported that 50 per cent of his pupils were undersized and underfed, poorly clad, and badly shod, and, seeing that only 18 per cent received free milk, and that the *grants to the Monmouthshire education authority* were insufficient to provide adequate necessities, what steps he proposed to take in the matter —Mr GEOFFREY SHAKESPEARE replied My attention has been called to the physical condition of the children in the boys' school at Blaina which is not satisfactory, though on my present information I cannot fully accept the head master's statement I should welcome increased provision of free milk in this and other schools in Monmouthshire, but I understand that this provision is restricted by the severe income scale at present in force This question has recently been discussed with representatives of the local education authority, and I understand that the authority are considering the question of introducing a more generous income scale

Mr JOHNSTON asked whether, if the hon gentleman could not accept the head master's statement on the matter, he was not prepared to accept the statement made by two of the medical officers of health of the county who re examined these children in January of this year and discovered that children of 15 were, on an average, 16 lb. under weight, and that 40 of the boys were sitting in school with damp feet, and that there was poverty and despair all over the district ?

Mr SHAKESPEARE said his attention had been called to that report, which did not bear out the statement of the head master He understood that a fund had been raised to provide boots for the children.

Mr JOHNSTON asked if the hon gentleman was not aware that the official inquiry showed that the condition of affairs was worse than in the original statement made by the head master ?

Mr SHAKESPEARE said that it did not approximate at all to the statement of the head master

Inspection of Offices by Local Authorities

Mr SHORT asked the Minister of Health whether he had yet circularised local authorities calling attention to the provisions of the Public Health Act, 1936 respecting *the conditions of offices and the need for periodical inspection*, and, if so, what had been the nature of the response

Mr HERBERT WILLIAMS asked the Minister of Health what steps were being taken by local authorities under the provisions of the Public Health Act, 1935, to ensure that the provisions of the Act in respect of offices were effectively enforced —Sir KINGSLEY WOOD replied A circular drawing the attention of local authorities to their powers and duties under the Act in respect of offices is in course of preparation and will be issued well in advance of Oct 1st next, the date on which the Act comes into force

PUBLIC HEALTH

Vital Statistics for 1936

THE Registrar General has issued a provisional statement of the figures for birth rate, death rate, and infant mortality for the year 1936

—	Birth rate	Death rate	Infant mortality-rate
England and Wales	14 8	12 1	59
122 county boroughs and great towns including London	14 9	12 3	63
143 smaller towns	15 3	11 7	55
London (administrative county)	13 7	12 5	66

The smaller towns are those with estimated resident populations of 25 000–50 000 at the 1931 census

Note —The birth and death rates for England and Wales as a whole are calculated on the estimated mid *1936* population, those for the towns aggregates and for London on the estimated mid *1935* populations The birth rate is based on live births the death rate on crude deaths

The birth rate for 1936 is 0 1 per thousand above that for 1935 and is 0 4 above that of 1933, the lowest recorded The crude death rate is 0 4 above that of 1935 and 0 7 above that of 1930, the lowest on record The infant mortality rate is 2 above that of 1935, which was the lowest recorded, and is the same as that of 1934, the previous lowest record The rates are provisional and are issued for the information of medical officers of health, but they are not likely to require substantial modification

Influenza

The Ministry of Health has again speeded up the weekly return In the great towns of England and Wales 1100 deaths from influenza were reported during the week ended Jan 16th The graph, it will be seen, still closely follows that for the epidemic of 1932–33 and must disappoint those who were led to believe that the peak of the epidemic was reached a week ago There is however now some indication that it will *not* reach the level of the 1933 peak. In any case it should be borne in mind that there is a lag of 10–14 days in the graph of deaths behind the graph of onsets and the deaths must continue to rise for some time after the epidemic has begun to wane.

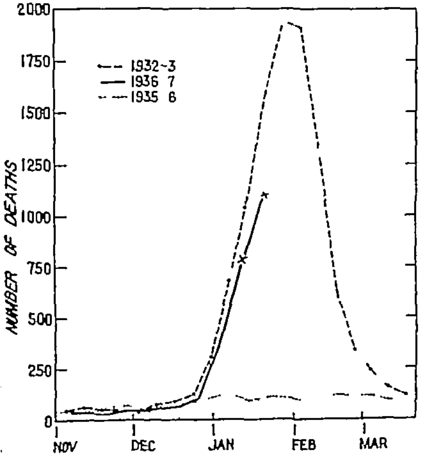
The impression of general mildness in the attacks is confirmed by the age distribution of the 768 deaths in the week ending Jan 9th

Ages	Deaths	Percentage of total.
0–24	47	6 1
25–44	92	12 0
45–64	262	34 1
65 and over	367	47 8
All	768	100 0

These figures show no movement towards the heavy mortality of young adults in the epidemic of 1918

We cannot yet give any precise up to-date figures for the distribution of deaths over different parts of the country, but a topographical analysis of the 768 deaths from influenza reported in the week ended Jan. 9th confirms the great preponderance already noted in the south-eastern area Of the total 311 occurred in London and 574 in Greater London The numbers in the Outer Ring were (in diminishing order) Willesden 23, West Ham 1[illegible] Ealing 16 Croydon 10, Tottenham 9 Heston and Isleworth Hornsey each 8, Hendon, Wembley each [illegible] Acton, Brentford, Leyton, Wimbledon each 6 Edmonton [illegible] Beckenham Southgate Wood Green each 4, [illegible] 3, Tottenham 2, Barking Mitcham each 1 Finchley (with 62 660 inhabitants) was the only town in the Outer Ring which reported no death Outside London the number of deaths (in diminishing order) was as follows Glasgow 33 Bradford 25, Leicester 24 Birmingham [illegible] Belfast 17, Bristol 16, Edinburgh and Leeds 1[illegible] Nottingham 12

In the absence of any exact regional figures last week from the Registrar General s department we may record the impression gained from reports which have reached us that the epidemic remains substantially the same in quantity and quality although abating in some localities and increasing in others In London the admissions to L.C.C. hospitals have dropped from 1600 to 900, the character of the attacks has not altered. The deaths in London rose from 311 to 344 in the week ending Jan 9th a large proportion being in old people In Brighton the position is unchanged except that bronchitis and otitis media are becoming more frequent complications Last week influenza reached Devon the cases there are running a short course mostly of the cerebral and/or respiratory type with some gastro-enteritis—the duration two to three days and only a short period of depression following; no serious complications In Wales there has been a sharp attack at Holyhead the worst experienced *since 1918 but of a type not serious to young people* schools and local places of amusement have been closed for the time In the north also the disease has spread somewhat but still in mild form At Bridlington contrary to the rule about half of the school-children seem to have been affected In the Newcastle district there has been a good deal of catarrhal bronchitis but no other complications and the deaths are not unusual for the season A report that half the inhabitants of Holy Island were stricken has proved on investigation to mean that while coughs and colds are evident in nearly every member of the community of 200 persons no one actually was very ill In Scotland the highest incidence has been in Glasgow where the deaths have been the highest recorded since 1920 In Edinburgh the attack rate remains the same and few children have been affected. But even the remotest parts of Scotland report inconvenience especially among light house keepers In Dublin there has been no extensive outbreak and few patients have sought hospital treatment The type is not severe the usual symptoms being headache muscular pains respiratory catarrh and brief pyrexia There is also in the city a good deal of severe bronchitis accompanied by tracheitis apparently unrelated to influenza as there is no myalgia or headache, and the attack is not followed by depression In Belfast the worst is reported over and in Cork the epidemic is said to be subsiding



Graph showing total deaths from influenza in the Great Towns on the last day of each week in three different years.

PLUS ÇA CHANGE

the more influenza remains the same In our issue of Jan. 21st 1837 it is remarked that ' the prevailing epidemic has become of so serious a character that we have felt it to be our duty to place on record a description of the malady as it has appeared in the district in which the office of THE LANCET is situated The surgeon of the parochial infirmary was able to give a statement week by week of patients receiving medical relief for the eastern division of St. Clement Danes the numbers suffering from influenza rising from 25 to 98 between December and January At no period it is said have so many persons been invalided in this locality and never has disorder of the animal functions been so general among the inhabitants A comparison is made with the typhus fever which raged in the same district during a portion of the last spring and although much more formidable *per se* was less dangerous in its complications The influenza affected persons of all habits rarely children until the epidemic was well advanced. Milder forms of the complaint consisted of sneezing nasal discharge sense of pressure and fullness at the frontal sinuses with headache and some degree of lassitude. These symptoms induced but very few to seek medical advice professional assistance indeed was neglected until the full establishment of the disease almost invariably indicated by the occurrence of cold shivers ' followed by pains in the head and limbs hoarseness, cough and prostration In several cases the disorder extended to members in the same family or house Uncomplicated cases however severe were not dangerous but when the disorder supervened on bronchitis death from asthenic congestion of the lungs was likely to occur A fortnight later a leading article sums up the outbreak which was then on the decline There is nothing about the symptoms and little about the treatment to distinguish it from present day practice

In every instance and at all times it evinced itself as a fever *sui generis* never even in its earliest stage, to be cut short by treatment as a common cold though capable by judicious management of being rendered in its subsequent progress much more mild —a sentence which (minus perhaps some commas) might have been written to-day The causation is summed up in the following words:

So far as enquiry has enabled us to form a judgment the disease is produced by some infectious poison *gaseous or miasmatous suspended in the atmosphere* favoured perhaps in its transmission from place to place by moisture and promoted in its reception by the action of cold debilitating the part to which the poison is applied But in a later article THE LANCET definitely hardened against the idea of influenza being propagated by contagion The unexampled rapidity with which it has overrun *localities* and even kingdoms renders it impossible to allow the assumption of transmission from one human body to another Nevertheless the interesting fact is recorded that one European State put British ships in quarantine for it

---

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JAN 9TH 1937

Notifications.—The following cases of infectious disease were notified during the week: Small-pox 0; scarlet fever 1817; diphtheria 12 5; enteric fever 31; pneumonia (primary or influenzal) 2333 puerperal fever, 33, puerperal pyrexia, 133, cerebrospinal fever, 34, acute poliomyelitis, 5, encephalitis lethargica, 5, dysentery, 37, ophthalmia neonatorum, 88 No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals for the London County Council on Jan 15th 1937 was 3898 which included Scarlet fever 895 diphtheria, 1033, measles 14 whooping cough 548 puerperal fever, 16 mothers (plus 5 babies) encephalitis lethargica, 284, poliomyelitis, 2 At St Margaret's Hospital there were 14 babies (plus 4 mothers) with ophthalmia neonatorum

Deaths—In 122 great towns, including London, there was no death from small-pox, 1 (1) from enteric fever, 7 (1) from measles, 5 (1) from scarlet fever, 21 (9) from whooping cough, 50 (13) from diphtheria, 31 (12) from diarrhœa and enteritis under two years, and 768 (311) from influenza. The figures in parentheses are those for London itself

Hull and Swansea each had two deaths from measles Manchester 2 from whooping cough Fatal cases of diphtheria were reported from 24 great towns, Liverpool 7, Manchester 4, St Helens 3

The number of stillbirths notified during the week was 261 (corresponding to a rate of 37 per 1000 total births), including 41 in London.

MEDICAL NEWS

University of Cambridge

The chair of physiology at the University will fall vacant on the retirement of Sir Joseph Barcroft at the end of September Candidates for the chair should communicate with the vice-chancellor before Feb 20th

The title of degree of B Chir has been conferred on M P Shackle and W F Young

Dr D V Davies and Dr W R M Morton have been appointed university demonstrators in anatomy for three years

University of London

At recent examinations the following candidates were successful —

D P H

Part I—J K Adranvala, D M Blair, Kathleen G Brimelow Joyce M Brockington P N Chatterjee A B Christie, Kitty K Conrad J S Cookson, Teresa I M Craig Iris M Cullum C F Cumings, B K De Silva Samuel Graham, Eva M Gray, H F Green R M M Hunter J D Lendrum S E D Masilamani B B Mukerjee Douglas Murray A F S Perera, Violet M Spiller, T S Szo J W P Thompson A F Turner H M van der Wall Sarah C B Walker L A F Wiles and Isabel A M Woods

University of Aberdeen

Dr John Stirling Young, professor of pathology in the Queen's University, Belfast, has been appointed to the chair of pathology in the University in the place of Prof Theodore Shennan who has resigned

Dr Young graduated in arts at the University of Glasgow in 1919 and B Sc in 1921 He took his medical degree with honours in 1923 and a year later was appointed assistant in the pathology department of the University of Glasgow and assistant pathologist at the Western Infirmary In 1927 he went to Leeds as reader in experimental pathology and assistant director of cancer research at the university Two years later he was awarded the Bellahouston medal for his M D thesis In 1932 he took up his present position During the war Dr Young served with the 8th Cameron Highlanders and later as captain and adjutant in the Black Watch He was awarded the Military Cross His contributions to pathological journals include studies of hyperplasia and metaplasia produced experimentally

Royal College of Surgeons of England

A meeting of the council was held on Jan 14th with Sir Cuthbert Wallace, the president, in the chair A resolution of condolence was passed on the death of Sir John Bland Sutton, formerly president of the College The Hallett prize was presented to Mr Robert Evan Owen Williams, of University College Hospital The president was elected to represent the College at the forthcoming Coronation ceremony Dr John Beattie, conservator of the museum and director of research, was appointed representative of the College on the Huxley memorial lecture committee Sir Arthur Keith, F R S, was reappointed as the representative of the College on the joint committee of anthropological research and teaching of the Royal Anthropological Institute Mr Eardley Holland was appointed to represent the College on the Central Midwives Board Mr L R Braithwaite was reappointed to the medical advisory committee of the British Health Resorts Association

The council entered into a contract with Messrs Higgs and Hill for the rebuilding of the upper floors of the College for the new Bernhard Baron research laboratories The council gratefully received a gift of £25 from Mr Walter Radcliffe M R C S for the purpose of cancer research, and a gift from Lord Moynihan of Leeds and Almina, Countess of Carnarvon, of the instruments used by the late Lord Moynihan at Alfred House The Cheltenham General and Eye Hospital was recognised under Sections 21 and 23 of the regulations relating to the education and examination of candidates for the diploma of fellow in respect of the post of house surgeon at the General Hospital A diploma of fellowship was granted to Reginald George Worcester, of the University of Melbourne and St Bartholomew's Hospital and a diploma of membership to Bernard Joseph Green, of the University of Liverpool

The following diplomas were granted jointly with the Royal College of Physicians of London —

Diploma in Public Health—R M Campbell A B Donald P J Doody M S A Hamid Enid A Hughes Vida L [illegible] Clement Muir Kulaveerasingham Somaskander, and H I Stevens

Diploma in Psychological Medicine—K C Bailey, B P Bhattacharjya C M Carlyle Gall L A Collins J G Dewar D S Fairweather, Hunter Gillies Lilian A Hayward B E Kirman E H Kitching A R McPherson M L Meade-King T A Ratcliffe D E Sands W W Sargant A S Thorley and D B Watson

Diploma in Laryngology and Otology—D L Brown, C W Dixon Narendranath Dutt, G A Jamieson and R N [illegible]

Lectures in Geology

Twelve Swiney lectures on Ice Ages will be delivered by Mr Frederick Walker, D Sc, at the Imperial College of Science Exhibition road, South Kensington, on Mondays, Wednesdays, and Fridays at 5 30 P M, from Feb 8th to March 24th Admission will be free

Society of Public Analysts

On Wednesday, Feb 3rd this society is holding a [illegible] meeting with the food group of the Society of Chemical Industry at the rooms of the Chemical Society, Burlington House, Piccadilly, W There will be two sessions, the first at 5 15 P M and another at 8 15 P M, which will be devoted to a discussion on the less known constituents of [illegible] and their examination

Laboratory for Testing Food

On Jan 19th Sir William Bragg, P R S, opened an extension of the joint laboratories at Holloway of the British Association of Research for the Cocoa, Chocolate, Sugar Confectionery, and Jam Trades and of the British Food Manufacturers' Research Association The laboratories were founded 15 years ago and the Government has contributed £50,000 and the members of the [illegible] about £110,000 towards the cost

Royal Sanitary Institute

A meeting of the institute will be held in the Town Hall, Halifax on Friday, Feb 12th, at 4 45 P M, when [illegible] J Pollard, M R C V S, will open a discussion on [illegible] and dairies legislation and Mr J W Beaumont, a discussion on housing past, present and future Visits [illegible] be made to the water purification plant, the new flats [illegible] working class women the disinfestation plant and the new isolation hospital where a short address on the future of the isolation hospital will be given by Dr G C F Roe, medical officer of health for Halifax.

Sir Ernest Graham Little has been elected an honorary member of the Polish Dermatological Society

St. Mary Abbots Hospital Kensington

On Jan. 15th the Bishop of Kensington opened a new operating theatre unit and an X ray department at this hospital A new underground service subway connects the new buildings with the hospital and enables patients to be conveyed under cover to the new theatre and X ray units. The extensions have cost about £13,500 Among those present was Miss Esther Rickards F.R.C.S chairman of London County Council hospital management sub committee who said since 1934 ten new operating theatres and X ray departments had been opened in London County Council hospitals.

New Readerships at Leeds

Our Leeds correspondent writes The two new posts of reader in medicine and reader in surgery which are being instituted by the University should prove very attractive The duties are intended to be those of research in the two subjects and especially of the correlation of clinical and laboratory methods It is suggested that applicants should not be more than 35 years of age and it is indicated that preference will be given to those candidates who possess either the membership of the Royal College of Physicians of London or the fellowship of the Royal College of Surgeons of England The salaries offered are £600 a year The duties will include a considerable amount of teaching and this is especially necessary in view of the increase in the number of students. Application has been made to the board of the Infirmary for the granting of facilities to the holders of the two posts to carry out the clinical parts of their duties within its walls and this has been readily granted.

Child Guidance Council

The third biennial child guidance inter-clinic conference will be held on Jan 29th and 30th at Friends House Euston road London N W and at B.M.A House Tavistock-square W C which is near by The secretary of the council Dr D R MacCalman may be addressed at Woburn House Upper Woburn place W C

The council have also arranged a vacation course on child psychology which will be held from March 31st to April 9th at Berridge House Fortune Green road London N W The programme will include lectures on normal emotional growth and its bearing on good mental health (Dr J R. Rees, Dr Henry Wilson Dr Grace Calver) clinical experience in dealing with behaviour difficulties (Dr William Moodie Dr D R MacCalman Dr Hamilton Pearson) and intellectual development and its relation to problems of learning (Miss L. G Fildes Mrs Susan Isaacs Miss M MacTaggart and Miss C Simmins) Further particulars of this course may also be had from the secretary

Schrötter's Centenary

On Jan 30th the University of Vienna and the Vienna Rhino-laryngological Society are to celebrate the centenary of Leopold von Schrötter who was born on Feb 5th 1837 He was one of the great pioneers of the specialty and the results of his researches and methods still have a place in modern laryngology Schrötter was the founder and first chief of the University laryngological clinic in Vienna, the first specialist clinic in the world He was also one of those who began the modern campaign against tuberculosis At Alland near Vienna he founded the first climato-dietetic establishment for tuberculous patients and this became a model for all similar institutions In the Arkadenhof of the University a marble memorial tablet with a medallion of Schrötter by Prof L R von Zumbusch will be unveiled Prof Arzt the rector of the University Prof Wilhelm Kerl the dean of the medical faculty Prof Josef Sorgo as a late pupil and assistant of Schrötter and Prof Hermann Marschik as laryngologist and president of the Vienna Rhino laryngological Society will pay tribute to the great man Replicas of the medallion and further particulars may be obtained from Prof M Weinberger Wien IX Brucknerstrasse 4

Congress in Algiers

The eighth Congrès International de Haute Culture Médicale will be held in Algiers from March 25th to April 6th. The work of the congress will be divided into six sections: infectious tropical and subtropical diseases (president Senator Maragliano Genoa) syphilis and dermatology (presidents Prof Milian and Prof Levaditi, Paris) cardiovascular diseases (president Prof Laubry Paris) hæmatology general medicine and social medicine (president Dr Haremann Paris) During the congress a meeting will be held to pay tribute to the work of Laveran Manson Ross Marchiafava Celli, and Grassi at which Prof Brumpt (Paris) Dr Sergent (Algiers) Dr Manson Bahr (London) and Mme Celli will take part Until March th Mr L. W Tomarkin the organiser may be addressed at the Institut Alfred Fournier Boulevard Saint Jacques 25 Paris, and afterwards care of the Gouvernement Général de l'Algérie Alger

NOTES, COMMENTS, AND ABSTRACTS

A MODIFIED BILLROTH I

Dr J. Schoemaker, professor of surgery at The Hague, gave the Hunterian lecture of the Hunterian Society at the Mansion House on Monday evening, setting out the principles and methods he had found successful in the surgical treatment of gastro-duodenal ulceration and inflammation. He began with an assurance that ulcers can be cured by medical treatment; only after failure of prolonged and regular medical treatment is it the physician's duty to hand his patient over to the surgeon. And he ended with the assurance that though the surgeon cannot cure all his patients he can heal more than 90 per cent. of them. The surgical treatment perfected by Schoemaker is a modification of the Billroth I operation of *partial gastrectomy*. Though fairly radical this aims at leaving behind a great part of the body and more than half of the greater curvature, thus impairing as little as possible the antiseptic and hæmopoietic functions of the stomach. Schoemaker claims that pernicious anæmia has never resulted from this operation. The first part of the duodenum, the pyloric antrum and the gastric canal (the *Magenstrasse* of the Germans) are removed, quasi-normal form and function being restored by suture of the free end of the duodenum to the lower part of the cut surface of the stomach. After the operation the stomach is smaller than it was, but otherwise Schoemaker claims that it is normal. The contents are well mixed and leave slowly by an orifice that takes on some of the functions of a pylorus. Gastritis and duodenitis do not occur and the jejunum is not suddenly flooded with partially digested stomach contents, as it is after either gastro-enterostomy or the *Billroth II operation*. Schoemaker showed films to illustrate the normal folds of a healthy gastric mucosa after operation by his method, contrasting them with the large folds found in the inflamed mucosa after gastro-enterostomy.

There was, he suggested, some justification for regarding gastro-enterostomy as a disease. Not only did it induce the risk of gastritis and jejunitis, but it did not stop bleeding, prevent perforation or remove the ulcer. The chance that an ulcer thus left in situ might later become malignant he regarded as too small seriously to influence the surgeon's judgment. Gastro-enterostomy had indeed a definite value in the treatment of ulcer; undertaken for stenosis it was the beginning of gastric surgery and the results had not been too bad. He performed it in cases where the patient was weak and tired out with vomiting, where he was so stout that satisfactory access to the site of operation was impracticable, and also in certain cases of very fixed ulcers of the duodenum where gastrectomy was considered too dangerous. A follow-up of gastro-enterostomies done in 1925 had shown that ten years after operation 60 per cent. had no stomach troubles, 20 per cent. suffered in minor degrees and 20 per cent. had no relief or had had recurrences. No case had died as a result of the operation. On the other hand 10 per cent. of gastro-enterostomy cases required a second operation. Faced with a perforated ulcer Schoemaker's advice to the surgeon was first to consider saving the patient's life; then if the opening was small, the interval since perforation was short, and the condition of the patient was good, partial gastrectomy was the best operation. He had been successful himself in a few such cases. For bleeding ulcer operation was not the first resort, but where bleeding recurred it must be done. The mortality was high—about 30 per cent.—but one must remember that operation was undertaken in the most serious cases and that it was difficult.

Prof. Schoemaker showed a film of partial gastrectomy as performed by him with his special gastric clamp. His critics have pointed to the danger of leakage at the angle where the gastro-duodenal junction meets the oblique line of sutured stomach surface. Having himself had no death from leakage he regards this danger as negligible. His results in 783 cases show 82 per cent. with no complaints, 7 per cent. with minor complaints, and 11 per cent. with no relief or recurrence of symptoms. He described the modifications required in cases of unusual difficulty and gave a special warning against reoperation for gastritis following gastrectomy. This, he said, could never be successful.

THE ANTI-JERRY BUILDERS

The Housing Improvement Association held a luncheon at the Langham Hotel on Jan. 14th at which the Minister of Health was present and spoke on a scheme for improving the standards of house building. The scheme, which is to be administered by the National House Builders Registration Council, includes the registration of house builders and the certification of houses built according to their specification. The council is made up of representatives of building societies, building trades employers and operatives, architects, and we learn that Dr. J. Greenwood Wilson, medical officer of health for Cardiff, has been invited to serve upon it. While all who are working for an improvement in housing standards will welcome the proposed specification and the certification, the Association will not rid us of the unscrupulous builder who does not join it and who will flourish as long as the State allows him to deliver his wares and the public is unwise enough to buy them. But some good will certainly come out of this movement in standardising and raising the level of work amongst builders of mass-produced low-priced properties for which there is a big demand, by reduction of competition through a standard specification. This should react upon the public demand for soundness rather than show, and promote the popularity of the certificate. We can only trust that those who advance money for house purchase will insist upon the certificate.

THE BATTERSEA STORM

As we related on Jan. 9th, the honorary appointments at Battersea General Hospital (formerly the Antivivisection Hospital) were recently thrown open to public competition. An independent selection committee nominated a new staff omitting many of the former members. At the last moment the hospital board refused to accept the selection committee's recommendations in toto and the chairman (Mr. *Parkes*) resigned in protest with two of his colleagues. The remaining members of the board who are carrying on the management of the hospital have now reappointed all those members of the staff whose applications were disapproved by the selection committee. In a letter to the press, however, Lord Ernest Hamilton (chairman before June, 1935) and Sir Herbert Lush Wilson say that the board has come to the sad conclusion that unless a sum approaching £10,000 can be obtained we should not be justified in carrying on the hospital beyond another month."

GREASY LENSES

A CORRESPONDENT writes: "For some time past I have possessed a stick of jeweller's rouge which was presented to me. Having tried it on various metals and glass I have discovered that if a small piece of washleather is rubbed with the stick of rouge it makes an excellent wiper for dirty or greasy spectacle lenses, and one which can quite easily be kept in the spectacle case. The colour of this kind of rouge is due to the ferric oxide (Fe_2O_3) obtained by calcinating sulphate of iron, which gives it its cleansing properties, and not to the addition of carthamin, cochineal or other pigment as is the case with cosmetic rouge."

NEW PREPARATIONS

"TABLOID" CALCIUM GLUCONATE AND IRON (Effervescent) is issued by Burroughs Wellcome and Co, Snow Hill Buildings, London, E C 1 One tabloid dissolved in a tumblerful of water makes an effervescent draught containing 20 grains of calcium gluconate and 3 grains of iron and ammonium citrate The preparation is recommended for adults or children who may be suffering from a deficiency of calcium and iron, and especially for women during pregnancy and lactation

BENERVA BRAND VITAMIN B_1 —On March 28th last we reviewed a paper in which W Ritchie Russell described his use of vitamin B_1, given by injection, in the treatment of polyneuritis and other nervous diseases (see *Edinb med J*, 1936, **43**, 315) The preparation employed has now been put on the market by Roche Products Ltd (51, Bowes road, N 13), under the name of Benerva Each ampoule of 1 0 c cm is stated to be equivalent to 500 international units of the vitamin, and the dose may be either hypodermic or intramuscular Success has been claimed in treating various forms of polyneuritis, subacute combined degeneration of the cord, anorexia nervosa, and neuritis in pregnancy The manufacturers also mention many other diseases and disorders in which they have reason to think vitamin B_1 useful

SALICYLYSIN LINIMENT and OINTMENT contain 20 per cent of glycol iodosalicylic ester, a new organic compound of iodine and salicylic acid in readily absorbable bases The makers (Allen and Hanburys Ltd, Bethnal Green, E 2) say that they are non-irritant, non-staining, and practically odourless, and recommend them for fibrositis, subacute or chronic articular rheumatism, arthritis, sprains, sciatica, and other forms of neuritis

GABASOL is a germicide said to have a Rideal-Walker coefficient of 4 5 when tested against carbolic acid, using *Bacillus typhosus* (Lister strain) The advantages claimed for it include a low surface tension, giving great penetrating power, and a nearly neutral reaction, "it is non-toxic, non-poisonous, non-staining, and has a pleasing and refreshing odour it promotes rapid healing without any trace of irritation or redness" The manufacturers are Gale, Baiss and Co, Ltd, Canterbury-road, S E 15

VITA LIVE NATURAL GRAPE JUICE —This is a bottled grape juice (non-alcoholic) concentrated by a low-temperature process so that it retains its ferments and vitamins The only change, it is claimed is that about five-sixths of the water is removed, and the large bottles are described as containing the equivalent of 17½ lb of fresh grapes The high content of grape sugar (glucose) ensures that the juice will keep indefinitely and gives it a high calorie value (1600 per pint) According to the manufacturers (Vita Products, Ltd, 30, Finsbury-square, E C 2) it is rich in iron in easily assimilable form and has a gentle laxative and diuretic action, they put it forward as a natural fruit juice for children—supplying them with vitamins A and B—as a tonic and energiser" as a flavouring, and as a beverage Diluted with water or soda-water it makes a very pleasant drink.

ADDRESSES AND ORIGINAL ARTICLES

RECENT AIDS TO THE PROGNOSIS OF PULMONARY TUBERCULOSIS *

BY R. R. TRAIL, M.C., M.D. Aberd., F.R.C.P. Lond.

PHYSICIAN TO THE ROYAL CHEST HOSPITAL AND TO THE PAPWORTH VILLAGE SETTLEMENT; LATE MEDICAL SUPERINTENDENT TO THE EDWARD VII SANATORIUM, MIDHURST

THE difficulty of the prognosis of pulmonary tuberculosis is so well established in medical literature that it is the theme of gloomy aphorisms by every well known writer on chest diseases in the latter half of last century. Samuel Gee summed up his ideas by saying: "Never attempt to forecast the probable duration of life in the case of phthisis. In this connexion there is only one thing that is sure, and that is, that if you do you will be wrong."

Even if an attempt was made at forecast in any individual case it was founded on mode of onset, while in type of established lesion it was, at best, only vaguely comparative. C. T. Williams and C. J. B. Williams (1897) are as dogmatic as any chest physicians of their own time in saying: "Acute phthisis is generally hopeless, while catarrhal phthisis, which is a primary feature of the tendency to excavation and the comparative absence of fibrosis, runs a less favourable course and a less limited duration compared with that of other chronic varieties, and especially fibroid"; and again: "It is in chronic tuberculous phthisis that the greatest triumphs of treatment have been attained when time, money, and perseverance are not lacking, and we can in most cases promise prolongation of life, and in others complete arrest of the disease. The patients who trace their diseases to pleurisy seem to have the best chances of life." This was no advance as against the statement of Fuller in 1862, when he said: "It can safely be said that the disease may kill in three weeks or a month from the date of its accession, or may run a chronic course of 20 or 30 years." Even at the beginning of this century, while Samuel West (1902) went so far as to state: "There is never any immediate danger to life unless with an onset of pneumothorax or hæmorrhage," his prognostic ideas were that: "Perfect cures are impossible, complete arrest cannot be expected in more than one or two per cent., and all we can hope for is that the progress will be held up by treatment."

All statements on the prognosis of phthisis are finally founded on the experience of the individual observer, restricted by current methods of diagnosis and treatment of the prevalent type of the disease. There is no reason to decry the pronouncements of these eminent physicians. Since their time we have advanced in methods of diagnosis, enormous strides have been made in treatment, from rest under sanatorium conditions up to active intervention by artificial pneumothorax and thoracoplasty, while we have the benefits of careful after-history reports and in recent years the development of laboratory aids from blood examinations. Moreover, we have no reason to crow over them even if we feel so inclined, for we are dealing with a disease in the majority of sufferers much more chronic than they encountered, with far less incidence of dangerous complications such as laryngeal involvement, more amenable to any form of treatment and often cured by none that we can claim part in, but even now too often already established to gross extent before our boasted advances have discovered its presence, so that we have missed what is of primary importance in both immediate and ultimate prognosis—an early diagnosis.

Such changing type of disease, together with further aids to assessment of lung destruction, especially radiography, led by natural consequence to the founding of prognosis much more on the extent of involvement than on the evidence of constitutional disturbances, until the latest report from Frimley Sanatorium (1935) is able to show that "The prognosis of chronic pulmonary tuberculosis varies directly with the extent of lung involved."

Sanatorium Treatment

The first work of any real value on the after-histories of patients treated on particular lines was that of Bardswell and Thompson in 1910. They made an intensive actuarial study of the experience of patients treated at Midhurst Sanatorium; their methods of "follow up" were so thorough that only minor improvements have been suggested, and their general conclusions have been in the main only strengthened by the many more recent investigations on similar lines.

Thus it is now accepted that mortality after sanatorium treatment is governed to a great extent by the condition in the first and second years after discharge, the two main factors being the comparatively early death of advanced cases, and the willingness or capacity of the patient to continue on the routine of life he has been taught during his residence. Not that this latter is any real new discovery; it is but a statistical verification of Fuller's statement that "It is neglect of rational means to sustain the general health for a sufficiently long time after improvement has commenced . . . which leads to the fearful mortality from phthisis."

Bardswell's figures showed that in cases that remain tubercle positive at the end of sanatorium treatment the ratio of actual deaths to the deaths expected is for males 21.8 in the general population, and for females 31.0. In cases which never had tubercle bacilli demonstrated in their sputum during their stay in the sanatorium he found the ratio to be 0.5 and 7.7 respectively. Clarke (1932) traced the after-histories of 700 patients of the Foster Green Hospital, Belfast; at the end of the 6th year after discharge only 22 per cent. positive sputum cases as against 72.5 per cent. negative cases were still alive. An investigation on 1700 patients treated at Midhurst Sanatorium between 1911 and 1929 (Trail and Stockman 1931) gives results which can be stated in slightly different form. The proportion alive 5 years after admission with positive sputum works out as follows for both sexes and all age groups combined, as based on the Turban-Gerhardt classification: Group I, 86.3 per cent.; Group II, 60 per cent.; Group III, 43 per cent. Although these percentages necessarily refer to a class of patient with advantages, both social and economic, in after-care as against the average working-class admissions to the public sanatoria of this country, they bear a very close resemblance to published statistics throughout Europe and America and state fairly accurately our present knowledge of the general prognosis for a given stage of the disease at the time of diagnosis. It must be very clearly understood, however, that they refer only to those sufferers willing and fortunate enough to be treated

---

[*] The Mitchell lecture for 1938 delivered before the Royal College of Physicians of London on Nov. 12th.

in a sanatorium The Frimley report states "We believe this to be the first occasion on which statistical evidence has been produced to show the value of sanatorium treatment". The graphs provided demonstrate "that the mortality experience of patients who have had the advantage of a course of sanatorium treatment is more favourable than that of members of the general population suffering from Pulmonary Tuberculosis' This conclusion had been hinted at by the workers of the Prussian and Hessian Railway Sanatorium who had found from the after history of patients in Group I and Group II followed up to a period of 4–6 years from the date of diagnosis, that fully 20 per cent more were alive amongst sanatorium treated patients

At the end of his report Bardswell expressed the opinion that something further than sanatorium treatment was necessary if the prognosis of phthisis was to be materially improved, it is a striking corollary that the last published sanatorium report (Hartley 1935) proves that there is a very little change in the outlook of the average chronic case over the past thirty years As we have already seen, and will discuss more fully later, the crux of the problem lies in the difficulties of after care, and of the differentiation in prognosis amongst patients of like social conditions and apparently similar extent of disease

Collapse Therapy

Shortly afterwards there began the accumulation of a vast experience of collapse therapy from artificial pneumothorax up to thoracoplasty, and later of intermediate measures of paralysis of the diaphragm through operations of crushing, cutting, and evulsion of the phrenic nerve

ARTIFICIAL PNEUMOTHORAX

Twenty years ago pneumothorax was hailed as the greatest advance in therapy since the institution of sanatorium treatment Even 14 years ago when Burrell and MacNalty (1922) produced their monograph under the ægis of the Medical Research Council opinions on its value were unanimously favourable, and its occasional dramatic success in the advanced case gave it a value still hard to undermine The present brings more sober judgment, relegates it to special conditions and the treatment of particular symptoms in the early and moderately advanced stages of the disease, and tries, still with small success, to depose it from the false position of a panacea and the last hope in a late diagnosis of established fibrotic lesions

Much of the still present hopefulness comes from insufficient study of the material for investigation, and the deduction of false conclusions from the comparison of conditions essentially unlike We now realise that the indications for the induction of pneumothorax immediately, and per se, relegate the patient to a particular category completely apart from his neighbour with evidently similar extent of disease, that his individual symptoms or his particular blood picture which do not alter with ordinary measures under supervised rest routine, automatically place him in a lower grade for both immediate and ultimate prognosis We have learned that should we, in our well meant enthusiasm, submit a patient to such treatment without due consideration of the amount of tissue destruction present at induction, or do not take to heart the lessons which the first few weeks of its continuance can teach us we may not only fail in our efforts to arrest the disease but be the cause of dangerous complications which hasten death and preclude him from the advantages he might have received from surgery

An investigation carried out at Midhurst Sanatorium (Trail and Stockman 1932) showed that a Group I case has a definitely better prognosis under pneumothorax than under ordinary sanatorium treatment, but while it warrants a similar conclusion in the average Group II case, it does not encourage its employment in Group III Moreover the figures quoted reflect the gravity of cases considered for induction in the lower categories, for even when continued treatment was possible 22 per cent. of Group II and 42 per cent of Group III cases were dead at the end of a period averaging 5 years from the date of discharge from the sanatorium They also teach us that in all probability some might have had a distinctly better chance of survival if they had been submitted for thoracoplasty either at the time of induction, or when it was recognised that continued treatment was producing inefficient collapse

This does not detract from the enormous value of pneumothorax within its prescribed indications, every country has provided us with evidence of the brightening of prognosis since its introduction, and an excellent digest can be found in the monograph where Bentley (1936) reviews the experience of the London County Council and attempts to assess the value of the treatment by comparing the fate of 677 cases with that of 3329 treated by conservative methods only He shows that there is a gain of 129 53 lives at the end of 3 years, that is, an increase of 19 1 per cent in the number alive over the expected number amongst those conservatively treated. A smaller group followed for five years shows a gain of 18 per cent at the end of 3 years and of 19 8 per cent at the end of 5 years

Similar results are seen in the Frimley report which compares very carefully ordinary sanatorium treatment with sanatorium treatment plus pneumothorax in patients in categories as nearly alike as can be reasonably assessed, and proves that the probability of survival is materially increased in those so treated, even cases relegated to the worst category of Group B III at the time of induction can show a higher survival rate than a control group derived from all groups combined What is still more interesting is that the treatment is shown to confer benefits enduring for at least 12 years and presumably for a longer period

A Midhurst series (Trail 1934) followed up over a period of from 3–9 years after discharge gives 80 per cent alive, since 70 per cent of these patients were at best only comparable with Group II cases on ordinary sanatorium routine, it follows that successful pneumothorax conferred an added chance of survival of some 20 per cent up to a period, on an average 5 years from the anniversary of the date of discharge

This percentage can be very materially improved in the near future The present judgment of the treatment as to its power to improve prognosis is based, for the most part, on a type of case we now see to be primarily unsuitable If the results of the London County Council, of Frimley and Midhurst Sanatoria, of Burrell and Fenton's cases (1930) and of a series collected by the Joint Tuberculosis Council are added together, it is seen that of 257 cases fully 60 per cent were already bilateral at the time of induction Bentley's report shows that the presence of even only slight contralateral disease materially reduces the chances of survival, and that while we must aim at complete collapse of the lung in every case, even incomplete collapse in a unilateral case gives a better end result than complete collapse where bilateral disease is present.

THORACOPLASTY

If we are agreed that the indications for pneumothorax place the patient in a definitely lower category and that we must therefore read our ultimate results in this light, the same argument but in greater degree must apply to present statistics of surgical collapse We see a changing attitude to the lesser measure which will *in the next ten years* most surely again enhance our opinion of its value as we apply the lessons of our mistakes in choice and management in like fashion we must remember that the major measure has suffered in the past from the expectancy of the impossible from thoracic surgeons most of whose results to date represent the attainments of a still rapidly developing technique practised on cases submitted as last hopes by despairing physicians.

Even then the results are heartening The combined figures of Archibald and Bull in America of Gravesen in Denmark and of Franke Kaystrom and Scherdtler in Germany can claim that 42 3 per cent of 1160 patients with thoracoplasty have been able to work without signs of disease for at least a year and Sauerbruch (1936) has had 40 6 per cent permanent cures among patients derived from every social class in Germany Tudor Edwards (1928) was able to claim even eight years ago that 37 3 per cent. of his cases were alive and well and that a further 17 per cent. were much improved The importance of such an advance in therapy is perhaps better understood by comparing the results of treatment at the Vejlefjord Sanatorium (Gravesen 1932) between 1901 and 1930 in Group III positive sputum cases; only 10 per cent of 1687 cases on ordinary sanatorium routine as against 34 per cent of 170 thoracoplasties became tubercle free.

It seems only reasonable to hope that with advancing surgical technique, the provision of adequate surgical units, and the better choice of case the prognosis of the patient with advanced unilateral disease will be improved by some 50 per cent in the next 10 years The realisation of this hope must lie with the physician as on him must continue to fall the brunt of selection He has now learned from experience in his patients what animal experiments had previously demonstrated that he need not fear more ultimate functional disturbance from collapse by rib resection than from complete compression by air He has seen that there is now a method of diminishing the continual auto-intoxication from secreting cavities and a reasonable hope of their ultimate closure by the relaxation of lung parenchyma and the consequent fillip to fibrosis through congestion and limitation of lymphatic circulation which artificial pneumothorax cannot always attain He must therefore in the future be more fair to his patient and to the surgeon neither in his enthusiasm submitting the former to operation while his disease is still exudative and his mediastinum unstable nor expecting the latter to come in only when he himself has been so conservative as to hang on to an inefficient pneumothorax until resistance has been seriously undermined

Much must depend on the attitude of the physician to the treatment of cavitation. To say that he must become more surgically minded that he must admit we have proved by sad experience the fallibility of the still too prevalent dictum that an attempt at pneumothorax must necessarily precede thoracoplasty does not mean that he must submit every case to operation without the most careful and individual consideration but it does mean that he has been inclined in several cases to expect too much from sanatorium treatment or incomplete pneumothorax with consequent waste of valuable time to the patient and useless expense of public money

The prognosis of cavitation is hedged about by the most contradictory evidence West could quote many cases with such lesion established to stethoscopic examination that lived up to twenty or more years but he also says It is the acute case that recovers and the chronic comparatively quiescent case that has a sudden fatal exacerbation. If modern methods of diagnosis show that a large number of such deaths must have occurred as they still occur by miliary spread from unsuspected cavity formation they also show why in one patient we may expect quiescence in another every prospect of complete closure by rest while in still another we must use every endeavour to attain such results by surgical *treatment*

New Methods of Examination

Apart from such aids to assessment of activity and to the consequent wisdom or necessity of active *intervention* as the *history the amount and bacillary* content of the sputum the temperature and the extent and nature of the lesion to physical and X ray findings can give us we have now further guides in serial radiographic examinations and laboratory tests carried out on the peripheral blood

In 1921 Dr Arthur Latham uttered his protest on the dangers of individualisation of prognosis on the extent of lung involvement alone by saying: The extent and character of physical signs is of little assistance in determining the activity of the disease the important things are the degree of toxæmia and the response of the individual. This was no mere return to the statement of West Constitutional symptoms show if present that the disease is active and their amount forms a measure of that activity; if they are absent the disease is either stationary or progressing very slowly In the light of present knowledge such a dictum is seen to contain all the inherent fallacies of proverbs founded on half truths The problem that exercised Latham has had some answer in the last fifteen years The insidiousness of the disease and its liability to symptomless spread both before its first clinical manifestations and after its apparent quiescence, have been demonstrated by Wingfield's work on serial X rays while valuable evidence is continually accumulating on the power of the peripheral blood to indicate the individual potential resistance toxæmia and state of metabolism since the pioneer experiments of Medlar Sabin and Westergren

THE SEDIMENTATION RATE

An article published by Westergren in 1921 resuscitated an interest in the sedimentation of the red blood-cells that can be traced back to Galen who first described the crusta sanguinis that was later to become the buffy coat behind the theory of blood letting Westergren demonstrated that citrated blood when placed in a tube and left for an hour shows a layer of clear plasma above the sedimented red cells in health measuring about 2 mm high for males and about [illegible] mm for females although the limits of normality have been found to be wide his figures stand as an accepted average Later he gave the necessary impetus to a vast amount of work on the value of this sedimentation rate as an aid to assessment of individual prognosis by suggesting that it would be "interesting to test the influence of the tuberculous infection on its stability "

Most observers are agreed that the test is of little value in diagnosis, although Cutler (1932) points out that it can indicate the presence of serious disease, not infrequently before such disease can be recognised by the usual clinical and laboratory methods In 5000 patients with raised rates, he found only 5 without some definite pathological condition In 1926, 360 consecutive admissions to Midhurst Sanatorium were investigated (Trail and Stone 1929) Of these, 318 were clinically tuberculous, and 97 per cent of them gave an increased sedimentation rate, the remaining 42 were clinically non-tuberculous, but 31 *per cent gave a raised rate*, which indicates that while an acceleration may be used in conjunction with clinical findings in diagnosis, other chest conditions give a high percentage of abnormal results, while a definitely tuberculous case may give a normal figure

Much of the work has been carried out in sanatoria, and has agreed in general with Roche's summary (1932) that "The blood sedimentation-rate is of proven value in the management of cases of pulmonary tuberculosis" Clegg (1929) and Cutler (1932) believe it to be an accurate measure of the activity of the lesion, and as important as pulse, weight, and temperature It may also be an index to the necessary duration of treatment (Trail 1933) and of the necessity to change its type by forewarning us of the onset of complications such as spread of disease before their usual clinical manifestations are present Bernard (1931) considers it to be the best single test yet evolved as an aid to prognosis, and ample proof can now be provided of its value as an indication of activity, of immediate outlook, and of response to treatment, so long as readings are taken at regular intervals over a long enough period The correlation of the clinical condition on admission and discharge with the sedimentation rates taken in this fashion, in 100 consecutive positive sputum cases on routine treatment at Midhurst Sanatorium (Trail and Stone 1929) proved that if a normal for both sexes is set at a reading up to 10 per cent of clear serum in one hour, a good immediate prognosis can be given for those with figures on admission up to 20 per cent Figures of from 20 per cent to 30 per cent warranted a guarded prognosis, as patients in this category seldom attained arrest of the disease within the usual period of sanatorium treatment, while those who gave readings between 30 per cent and 40 per cent and over were usually stationary or worse at the end of that time This same observation showed that the index was superior to the usual "exercise test" on pulse and temperature and led to the following conclusions

(1) A patient with unilateral disease and a sedimentation rate beyond 20 per cent on admission not lessening with a month's absolute rest ought to be seriously considered for collapse therapy

(2) Bilateral cases with a rate above 30 per cent *similarly not improving are unlikely to* be benefited by continued routine sanatorium treatment

(3) All cases with a falling rate ought to be given a chance of further treatment, and

(4) A regularly repeated sedimentation rate is a better indication of immediate prognosis than changes in weight, and even than the presence or absence of tubercle bacilli in the sputum

This last conclusion suggested an after-history investigation and 500 cases were followed up for 2–6 years after discharge (Trail 1933) The result showed that considerable attention must be paid to the test in assessing ultimate prognosis, as in many cases it was evidently superior to the usual guides of physical signs, temperature, pulse, sputum tests, and fitness for exercise By such accepted criteria 92 of the 500 were making satisfactory progress as the result of their treatment, yet it was found that their after history was no different from that of 29 patients who were in the same categories by virtue of their blood tests, but who because of raised temperature had been kept on bed rest during the whole of their residence In both groups the ultimate prognosis became increasingly grave with the higher rates of sedimentation The final deduction was that to enter a sanatorium with a rate of *over 20 per cent and leave with one of over 10 per* cent must warrant a serious outlook, that such seriousness increases with open cases, and particularly those who remain so in spite of treatment, but that nevertheless the rule applies to every case of clinical tuberculosis whether open or closed. Of patients who left the sanatorium with a rate of over 20 per cent, fully 50 per cent of those who had remained tubercle positive were dead at the end of the period of observation, if they had become tubercle free during treatment, 25 per cent were dead, while in cases where tubercle bacilli had never been demonstrated in the sputum but who were definitely clinically tuberculous, fully 20 per cent were dead On the other hand, it appears to be better to remain positive and to secure a fall in the rate to under 10 per cent than never to have had positive sputum and leave the sanatorium with a discharge figure of over 10 per cent

THE MONOCYTE-LYMPHOCYTE RATIO AND THE VON BONSDORFF COUNT

Since the introduction of the sedimentation test, further blood examinations have been studied, particularly the monocyte and lymphocyte ratio. Many workers now believe that this ratio is a definite indication of pathogenesis in that a reciprocal fall in the lymphocytes accompanies a rise in monocytes in progressive disease, while the converse is true in the presence of healing or receding lesions, in other words, that if the absolute number of monocytes approaches that of the lymphocytes so that the comparative ratio is high, prognosis is not good. The reasoning is founded on the belief that the epithelioid and Langhan's giant cell of the tubercle are derived from the monocyte in the circulating blood, so that when phthisis is spreading the increasing monocytes in the tissues are reflected in the blood stream at the expense of the lymphocytes, while the opposite takes place when healing commences

Others have studied the von Bonsdorff count, which is a modification of the Arneth index, and consists in the enumeration of the total number of separate nuclei in the first 100 polymorphs counted, variations in the figure found represent the degree of "shift to the left" which is present

Many articles have been written showing a superiority *for each of these three blood* tests over the other two as an index to prognosis, whereas they are essentially in agreement It only requires a series of counts to be taken in the same patient over a sufficient period of time to prove that variations may occur in one not paralleled by the others. This does not mean that they are necessarily contradictory, *as* they really demonstrate *three* different aspects of the same process

Houghton (1935) has done a considerable amount of work on these lines, and believes that the monocyte lymphocyte ratio and the von Bonsdorff count taken together can show pathological changes earlier than the sedimentation rate He has sufficient proof to formulate the theory that the differential count indicates potential resistance to the disease, while the sedimentation rate and the von Bonsdorff count reflect the condition which is the result of the lesion the former measuring the amount of constitutional disturbance and consequent state of metabolism and the latter the toxæmia which is the result of the activity Further he has found it possible to combine all these tests and to reduce them to a common denominator which he calls a hæmogram, and which can serve not only as a basis of convenient comparison between cases but also as a fairly accurate sliding-scale of the pathological status of the patient at any given point in his treatment

Such work gives great hope that in the near future a further research into the use of these combined tests will solve many problems on the indications for treatment and the opportune moment for their employment which still confront the physician As they already provide an explanation for the longevity of the patient who has gross extent of disease and for the breakdown within a short period of others who had apparently reached quiescence as judged by other standards so they give us great assistance in assessing the true pathological status of those still under treatment We can now prognose that the type of case which is likely to improve most rapidly in its blood picture by the application of collapse therapy is one where there is severe toxæmia as evidenced by a low von Bonsdorff count but a good potential resistance and power of fibrosis in a high lymphocyte percentage while the metabolism and general condition are shown to be able to stand active intervention as there is a low sedimentation rate.

In the same way changes in the blood picture produced by minor measures warrant a forecast of the probable result of major measures where an improved von Bonsdorff count and a higher lymphocyte percentage have been attained by phrenic evulsion still further improvement may be expected from thoracoplasty On the other hand if deterioration in these tests is shown during the re expansion of a pneumothorax it is evidence of the continued activity of the disease and of the necessity of recompression of the lung It also follows that their use can be very properly extended to the field of after care.

After care

We have already seen that the most dangerous year for the sanatorium treated patient is that following his discharge There is no guarantee that the same insidiousness will not characterise a re exacerbation as all too commonly precedes the earliest clinical manifestation of an already established lesion and present methods of diagnosis of both conditions too often fail to reveal their presence before the extent of involvement is so great that the patient is past the stage of possible arrest from collapse therapy

Not the least of the advantages to the case of artificial pneumothorax lies in the continual and expert supervision which he automatically receives for a period of some three years following the induction Frequent screening and film examinations discover complications or fresh foci before the patient is aware of their presence so that prompt treatment is undertaken The pronounced effect on ultimate prognosis needs no comment except in so far as it brings a lesson which we have been slow to learn in that our after-care schemes in general are withholding from all other ex patients the benefits conferred on the few fortunate enough to receive active treatment. Until such benefits are universally provided we must continue with the present results of sanatorium treatment that have shown little alteration since the beginning of this century

Early Diagnosis

What is true of after care is true of diagnosis Of all pulmonary cases treated by the London County Council during 1921 only 35·4 per cent. were diagnosed *before the disease had progressed beyond the* early stages a review for the years 1927–31 inclusive shows this proportion to remain practically steady If this instructive though unpleasant statement is taken in conjunction with the fact that phthisis shows no real improvement in incidence or death rate over the last thirty years in adolescents and young adults between the ages of 15 and 35 it must follow that the hope for the future lies in diagnosis at a preclinical stage.

From the study of the histories of sanatorium patients it is evident that it is not yet generally realised that a pleural effusion is in most cases an infection of the lung periphery by contiguity and extension Bowditch found that of 90 cases, 32 died of phthisis and Allard and Koster that of 2123 patients with established lesions 30 per cent had a history of previous pleurisy The records of Midhurst Sanatorium between 1924 and 1933 show an interesting point of all patients admitted during that period with definite pulmonary diseases no less than 26·6 per cent had a history of pleurisy three to four years before admission but of 61 admitted for pleurisy only 3 that is, 5 per cent have since developed any further signs or symptoms of tuberculosis. This is upheld by the findings of Gaarde (1930) who reports that of 68 cases of pleural effusion who had at least four months rest 43 recovered completely but that of 17 with less than two months rest 11 were dead within the same period of observation

RADIOGRAPHY

The same arguments apply to many cases of hæmoptysis of long-standing indigestion amenor*rhœa and fistula in ano for if all such* were submitted to screen and film examination by a competent chest radiologist, a large proportion would be found to have latent or even active disease often established to an alarming extent. That it is already present though unsuspected, and can be diagnosed in the symptomless stage has been demonstrated by the intensive work of Fellowes (1934) Hetherington McPhedran Landis and Opie (1929) Their combined results show a percentage of latent disease of fully 1 per cent in adolescents and of 3·6 per cent *at older ages in the apparently healthy Hetherington* discovered 1 per cent of such foci in adolescent children and a research at Philadelphia University (1931) showed amongst medical students a continuous increase in incidence in successive years of study of from 4 per cent in the first year to as much as 21 per cent in the fourth year In this country Wingfield and McPherson (1930) studied 2381 adolescents between the ages of 14 and 21 all of whom were apparently in normal health, and found a positive result in 0·65 per cent which was increased to 1·08 per cent, when they included abnormal film that could not be explained on any other basis These facts demonstrate that we have at hand a method of early diagnosis that can completely alter the prognosis of pulmonary tuberculosis At present we are spending enormous amounts of money in attempts to patch up those already seriously damaged by a condition which might have been discovered while it was still latent, and on the disasters of relapse and reactivity that present themselves in fully 50 per cent of treated cases within three years of reaching apparent quiescence It is almost certain that the expense of the tuberculosis services would be definitely reduced within a period of twenty years if we now began detecting by routine radiography latent disease in adolescents and young adults, what is far more important is that we should certainly have an enormous effect on the prognosis of phthisis, and not only save life, but also alleviate the continuing amount of worry and distress from the ravages of this disease, at the age when we find a sustained morbidity and mortality in spite of all other methods of diagnosis at present employed

Conclusions

We can now sum up the present position in the light of work done in the past twenty years, and, profiting as much by our failures as by our successes, visualise such application of recent work on earlier diagnosis, the employment of special treatments, and the value of after care as ought to brighten prognosis very materially in the near future

The benefits which routine sanatorium treatment can confer are now established by a comparison of the fate of its ex patients with that of the tuberculous in the general population The expectation of survival for five years in those so treated can be stated in accordance with their groupings on extent of disease at admission as 80 per cent in Group I, 66 per cent in Group II, and 35 per cent in Group III We know from statistics of end results of pneumothorax treatment that such expectation of life has been improved by some 20 per cent in Group II and Group III cases combined, even though fully 60 per cent of the recipients were not unilateral cases at the time of induction, and that 40 per cent of its failures have been given an equal added chance by thoracoplasty despite the fact that this measure has been judged by still harsher standards of selection Both these methods of active intervention have shown their power to improve on the expected value of routine sanatorium treatment in unilateral cases, which by their very selection were relegated to a category of graver outlook as against their fellow patients of evidently similar extent of lung involvement

From laboratory tests on peripheral blood we are now able to assess individual resistance, powers of recovery, and toxæmia, to choose the case that is likely to improve on routine treatment and to forecast its length, to select our cases for special treatments, and to state with more exactitude than we could ten years ago immediate and ultimate prognosis In addition they have shown us why results of sanatorium treatment are practically parallel in many patients of entirely different social standard and therefore of presumably different categories for after care

We have yet to apply several lessons of these advances In view of the static results in routine treatment over the past thirty years, we must aim at conferring on all our patients the benefits of the after-care that have been the foundation of the successes of active treatment in automatic expert supervision including serial radiography and blood tests, we must become more surgically minded i pulmonary tuberculosis as we have already becom more medically minded in surgical tuberculosis, an if we are to have any effect on the unchanging and ver gloomy picture of morbidity and mortality in adole cent and early adult life, we must employ X ra diagnosis, or at least institute further research i its value in the discovery of the disease while it still latent and symptomless

THE IMMUNISING POTENCY OF ANTIGENIC COMPONENTS ISOLATED FROM DIFFERENT STRAINS OF *BACT TYPHOSUM*

By W W C Topley, H Raistrick,

J Wilson, M Stacey, S W Challinor,

and R O J Clark

(From the London School of Hygiene and Tropical Medicine)

In an earlier series of papers (Raistrick and Topl 1934, Delafield 1934, Martin 1934) we and o colleagues reported the isolation from *Bacter typhi murium* (*Bact aertrycke*) of a fraction whi on injection into mice, induces an active antibacter immunity of the same order as that induced by th whole bacterial cells This fraction is toxic for and for rabbits In addition to increasing t resistance of mice to living virulent bacilli, its injec in minute amounts, renders them resistant to a f minimal lethal doses of the toxic fraction it An antitoxic immunity of this low order has be recorded by many workers who have studied t reactions of the so called bacterial endotoxins is sharply differentiated from the high grade an toxic immunity that is readily developed again the so called exotoxins, such as those of *Cory bacterium diphtheriæ* and *Cl tetani*, in which animal may be rendered resistant to a thousand or more minimal lethal doses. Chemically this toxic and antigenic component consists of a complex polysaccharide linked to a component containing nitrogen phosphorus sulphur and fatty acids which is perhaps, a phosphatide

Boivin and his colleagues (1933 1934 1935 1936) were independently approaching the same problem by a different method at about the same time as ourselves and their initial results were published some months before our own. Subsequent studies have made it clear that the component which we have isolated by acetone treatment of the bacterial bodies followed by tryptic digestion and alcohol precipitation is identical in all its essential properties with the component isolated by them by extraction with trichloracetic acid followed by alcohol precipitation Both their studies and our own leave little doubt that this component represents the polysaccharide somatic antigen of the normal smooth form of *Bact typhi murium* in its naturally occurring state and at the same time constitutes the main endotoxin When the complex antigen is heated at 100 C with decinormal acetic acid it splits into the polysaccharide component which remains in solution, and the phosphatide component which is precipitated. The polysaccharide component is entirely non toxic for mice The phosphatide component retains some toxicity but is much less toxic than the complete antigen

Antigenic components of the same general type may as Boivin and his colleagues (1933) have shown be isolated from a variety of organisms including the members of the typhoid paratyphoid group With the exception of the antigen of *Bact typhi murium* (*Bact aertrycke*) and of *Bact enteritidis* (*Bact gaertneri*) none of these components have yet been subjected to any detailed study

The recent investigations of Felix and his colleagues (Felix and Pitt 1934a and b 1935 Felix Bhatnagar and Pitt 1934 Felix and Bhatnagar 1935) on the so called Vi antigen of *Bact typhosum* and the studies of Perry Findlay and Bensted (1933 1934) on the efficacy of various typhoid strains as immunising agents in mice have raised problems which seemed susceptible to attack along the lines we had followed in our studies on *Bact typhi murium* and the practical importance of obtaining a reliable immunising agent as a prophylactic against human typhoid made it desirable that this possibility should be explored.

The present position in regard to immunisation with whole bacterial cells may be briefly summarised as follows Felix and his colleagues have shown that certain smooth strains of *Bact typhosum* are differentiated from many of the ordinary laboratory strains by being very slightly agglutinable in antisera containing agglutinins to the somatic (O) antigen These O inagglutinable strains are relatively virulent for mice while the ordinary O agglutinable strains are relatively avirulent The O inagglutinability of the mouse virulent strains is determined by the presence of an additional antigenic component—Felix s Vi antigen This component is relatively heat labile and Vi strains subjected to temperatures much over 60 C become freely agglutinable with an O antiserum When Vi bacilli killed in various ways are injected into mice they induce an effective active immunity against the subsequent injection of living Vi bacilli Killed vaccines prepared from smooth O strains however have been found by the workers referred to above to be entirely or relatively ineffective in inducing an active immunity In this case therefore it is not sufficient to use a smooth strain containing the ordinary heat-stable smooth somatic antigen The Vi antigen must also be present. There are certain reported findings which are at the moment not easy to reconcile with one another Thus, living Vi bacilli injected into the rabbit lead to the production of Vi agglutinins which act specifically on the Vi antigen as well as of O agglutinins Such antisera promote phagocytosis of Vi bacilli in vitro and exert a protective action against them in vivo The injection of formol killed Vi cultures into rabbits induces the formation of Vi agglutinins but the antisera so prepared have been found to lack protective power in vivo and phagocytosis promoting activity in vitro The injection into rabbits of Vi bacilli killed by heating at 58 C has failed to stimulate the production of Vi agglutinins except to a trivial degree and inconstantly and such antisera have been found to have no protective power It has however been the experience of Felix himself (see Felix and Pitt 1934b) of Perry Findlay and Bensted and of other workers (see Schütze 1936) that Vi bacilli killed in a variety of ways including killing by formol and by exposure to moderately high temperatures are fully effective in the induction in mice of an active immunity to living Vi bacilli It may be noted that doubts have been raised as to whether the Vi antigen can properly be regarded as determining virulence in the usually accepted sense (see Kauffmann 1935–36 1936 Ørskov and Kauffmann 1936) There is general agreement that the minimal lethal dose for mice of living Vi bacilli is much smaller than the *minimal lethal dose of O bacilli from which the* Vi antigen is absent (50–200 million as compared with 1000 to 2000 million); but the M.L.D of the Vi strains remains relatively high and almost certainly induces some degree of directly toxic effect. It should also be noted that strains intermediate between the pure Vi form and the pure O form are very frequent, and that the recorded results suggest that the immunising efficacy of any given strain is directly related to its content in Vi antigen

Experimental

The strains used in these experiments have been a rejuvenated Rawlings strain (R R) for which we are indebted to Major General Marrian Perry of the Royal Army Medical College and the well known H901 strain The R.R strain is inagglutinable by an O antiserum when tested in the form of a young living broth culture at 37 C (see Craigie and Brandon 1936) The 901 strain is readily agglutinable The minimal (average) lethal dose of the R R strain for mice weighing 18 22 g the bacilli being injected intraperitoneally is rather less than 100 million bacilli. The corresponding dose of the 901 strain is rather more than 1000 million bacilli. The R R strain is therefore of the Vi type the 901 strain of the O type or more strictly the H–O type

From each of these strains we have prepared a purified antigen by the same methods as we employed in our studies on *Bact typhi murium* Full detail of these methods and of the chemical properties of the antigens isolated will be published elsewhere For the moment it will suffice to note that the typhoid bacilli are killed by treatment with acetone and then submitted to full tryptic digestion The digest after clearing by centrifugation is submitted to alcohol precipitation The antigenically active fraction is flocculated by 68 per cent alcohol and for this reason, we have provisionally labelled it F68 This fraction is further purified by repeated alcoholic precipitation, and is then treated with oxalic acid which removes an appreciable amount of calcium which is present The antigen is further purified by several alcoholic precipitations from acid and neutral solutions It is with these components (R R /F68 and 901/F68) that the following experiments have been performed The yields of purified antigen obtained from the R R and 901 strains of *Bact typhosum* and from *Bact typhi murium* were in each case from 15–20 per cent of the weight of the dry bodies

Reverting for the moment to the tentative conclusion of Ørskov and Kauffmann, that the relatively high pathogenicity of Vi strains depends on toxicity rather than on virulence, we may note that the F68 antigen from the Vi (R R) strain has not, in our hands, proved more toxic than the F68 antigen from the O (901) strain Indeed, in the few comparative tests we have made, the reverse has been the case

THE IMMUNISING POTENCY OF R R /F68

The first experiment was designed to test whether an F68 fraction isolated from a Vi strain of *Bact typhosum* would induce an active immunity of the same order as that induced by the whole bacterial cells

The general plan of this experiment, and of those recorded later, has been the same as that followed in all our earlier studies A number of mice sufficient to allow for a few deaths during immunisation have been injected with two or more doses of the fraction, or fractions, under study, the injections being given at weekly intervals One week after the last immunising dose, the mice, in batches of 30, have been injected intraperitoneally with living Vi bacilli (strain R R) in a dose of 500 million At the same time we have tested numerically equal batches of non immunised controls The standard dose of purified antigen has been 0 017 mg The dose of bacterial cells, killed by the addition of 0 25 per cent formol and heating at 55° C for 1 hour, has been 500 million

In this experiment three immunising injections were given intraperitoneally Two groups of mice immunised with each reagent were tested, and two groups of controls All mice were observed for 7 days after receiving the test dose of living bacilli though deaths very rarely occurred after the third day

The results of this experiment are summarised in Table I, and need little comment Both the whole bacterial cells, and the purified antigen derived from them induce an effective immunity to living Vi bacilli The differences between the immunised and and non immunised groups are well beyond the limits required for statistical significance There is no significant difference between the degree of immunity induced by the purified antigen and by the whole bacteria

TABLE I

Showing the relative immunising potency of killed bacterial cells from a Vi strain of Bact typhosum *(R R) and of a purified F68 antigen from the same strain*

Group No	Immunising agent	No of mice in group	No of mice dying
1	Whole bacteria	30	1
2	Whole bacteria	30	1
3	F68	30	3
4	F68	30	0
5	Nil (controls)	30	23
6	Nil (controls)	30	25

THE RELATIVE IMMUNISING POTENCY OF THE VI (R R) AND O (901) ANTIGENS

In regard to the immunising potency of whole bacterial cells from the Vi (R R) and 901 strains, and of the purified antigens derived from them, our results are not in entire accord with the general conclusions of Felix and his colleagues, since we have found the 901 strain, and the purified antigen derived from it, to possess a significant degree of immunising potency They are, however, in accord with the actual experimental results reported by Felix and Pitt (1934b), and with the important conclusion of Felix and his colleagues, of Perry, Findlay and Bensted, and of other workers, that Vi strains of *Bact typhosum* are much more effective in inducing an active immunity in mice than are mouse avirulent strains, from which the Vi antigen is absent The degree of difference observed seems to depend on the route by which the immunising injections are given, and on the number of doses administered

In all the following experiments a uniform dose of 0 017 mg of the antigen under test has been employed, or of 500 × 10^6 bacilli killed by formol and heat. The immunising injections have been given at weekly intervals, and a test dose of 500 × 10^6 living Vi (R R) bacilli has been given one week after the last immunising dose The results may conveniently be summarised in tabular form (Tables II III and IV).

(*a*) *Two immunising doses given subcutaneously*—The results are shown in Table II Under these conditions the killed Vi (R R) bacteria, and the F68 antigen derived from them, induce an effective immunity The O (901) bacteria, and the F68 antigen derived from them, are quite ineffective These findings, so far as the relative potency of the whole bacterial cells is concerned, confirm those reported by Felix and Pitt (1934b) The purified antigen derived from the R R strain appears to be slightly less effective than the whole bacterial cells , but the observed difference is not statistically significant

TABLE II

Showing the immunising potency of whole bacilli and F68 antigens from a Vi strain (R R) and an O strain (901) when two subcutaneous immunising doses were employed.

Group No	Immunising agent	No of mice in group	No of mice dying
1	R R whole bacteria	30	1
2	901 whole bacteria	30	9
3	R R /F68	30	5
4	901/F68	30	25
5	Nil (controls)	30	2

TABLE III

Showing the immunising potency of whole bacilli and F68 antigens from a Vi strain (R R) and an O strain (901) when two intraperitoneal doses were employed

Group No	Immunising agent	No of mice in group	No of mice dying
1	R R whole bacteria	30	0
2	901 whole bacteria	30	16

4	901/F68	30	15
5	Nil (controls)	30	2

(*b*) *Two immunising doses given intraperitoneally*—The results are summarised in Table III The whole

R R bacteria, and the purified antigen derived from them again induce a highly effective active immunity; but when two immunising doses are given intraperitoneally instead of subcutaneously the 901 bacteria, and the purified antigen derived from them are by no means without effect The difference between the numbers of mice dying in the control group and in the group immunised with 901 bacilli is 11 and the standard error of this difference is 3 40 giving a ratio of 3 15 : 1 and hence amply fulfilling the criterion of statistical significance. The corresponding difference for the control and 901/F68 groups is 12 and the Difference/S E ratio is 3 38 1

There is no evidence of any difference in immunising potency between the whole bacteria and the purified antigens derived from them

(c) *Three immunising injections given intraperitoneally* —The results are summarised in Table IV Under these conditions the whole 901 bacilli and the purified antigen derived from them induce an immunity against living Vi bacilli of approximately the same order as that induced by the R R bacilli or by the R R antigen. In each case the immunity induced by the purified antigen is slightly but insignificantly less than that induced by the killed bacterial cells.

TABLE IV

Showing the immunising potency of whole bacilli and F68 antigens from a Vi strain (R R) and an O strain (901) when three intraperitoneal injections were employed

THE PROTECTIVE PROPERTIES OF R R./F68 AND 901/F68 ANTISERA

The results obtained with these antisera were somewhat surprising Rabbits were injected with the fractions in question receiving 0 1 mg 0 2 mg 0 5 mg and 0 5 mg per kg body weight of one or other antigen weekly doses being given intravenously One week after the fourth immunising injection the rabbits were bled and their sera examined They showed O agglutinin titres for *Bact typhosum* varying from 1 : 640 to 1 : 1280 Most of them failed to agglutinate Vi suspensions of *Bact typhosum* or agglutinated them only to very low titre (1 10) and incompletely The serum of one rabbit that had been immunised with R R /F68 however gave complete agglutination of a Vi suspension at 1 80 and a trace at 1 160 Judging from the experience of Felix Bhatnagar and Pitt (1934) this titre is definitely above the limit of normal Vi agglutinins and it would seem that we must regard the rabbit in question as having produced Vi antibody in response to the injection of the F68 antigen derived from the Vi (R R) strain This serum and the serum of a rabbit immunised with the 901 antigen which showed incomplete agglutination with Vi bacilli at a titre of 1 : 10 were tested for their protective action in mice 30 mice were given a subcutaneous injection of 0 25 c cm of the anti R R /F68 serum 30 were given a similar dose of the anti 901/F68 antiserum and 30 an injection of normal rabbit serum. Next day these 90 mice, and 30 normal mice that had received no serum were injected intraperitoneally with 500 × 10^6 living R R bacilli.

The results are shown in Table V Both antisera exerted a very definite protective action The normal rabbit serum exerted none The anti 901/F68 serum appears to be slightly less effective than the anti R R /F68 antiserum but the difference is not significant

TABLE V

Showing the protective action against living Vi bacilli of rabbit antisera prepared against R R F68 and 901/F68

No of group	Serum	No of mice in group	No of mice dying
1	Anti R R /F68	30	4
2	Anti 901/F68	30	8
3	Normal serum (control)	30	27
4	No serum (control)	30	[illegible]

THE CHEMICAL PROPERTIES OF THE R.R /F68 AND 901/F68 ANTIGENS

It has been shown above that both the R R /F68 antigen and the 901/F68 antigen have a definite immunising effect but that the R R /F68 antigen is significantly more potent When mice are immunised by two subcutaneous doses of 0·017 mg the R R /F68 antigen remains fully effective while the 901/F68 antigen is quite ineffective It is of obvious interest to inquire whether this difference in immunising efficiency is associated with any detectable difference in chemical behaviour or structure The chemical analysis of these antigenic components is as yet in its earliest stages; but it is already clear that the chemical properties of R R /F68 differ significantly from those of 901/F68 and of the F68 fraction from *Bact typhi murium*

All three antigens are fine white powders which on dispersion in water give rise to opalescent solutions All contain nitrogen (R R./F68 5 2 5 3 4 8 per cent in three different preparations 901/F68 4 9 5 1 per cent *Bact typhi murium* F68 4 3 4 8 4 2 per cent) and all contain ash (R.R /F68 2 5 per cent. ; 901/F68 4·0 per cent ; *Bact typhi murium* F68 4 3 per cent)

0 4 per cent aqueous solution of the three antigens give the following reactions —

(a) All of them give a heavy white precipitate with basic lead acetate

(b) *None of them gives a precipitate with any of the* following reagents sulphosalicylic acid trichloracetic acid Esbach's reagent magnesia mixture silver nitrate the sulphates of nickel cobalt and cadmium and the chlorides of barium and mercury (mercuric)

(c) Precipitates are given by R R./F68 but not by either 901/F68 or *Bact typhi murium* F68 with the following reagents: phosphotungstic acid in [illegible] per cent H_2SO_4 neutral lead acetate uranium acetate mercuric acetate and aluminium sulphate

(d) All three antigens give positive Millon *Biuret* Ninhydrin and Molisch reactions but none of them reduce Fehling's solution

It is obvious from a consideration of the above results that while the 901/F68 antigen and the *Bact typhi murium* F68 antigen are indistinguishable by the chemical tests referred to above the R R /F68 antigen differs in many important chemical respects from the other two The difference is also clearly shown by the behaviour of the three antigens on mild hydrolysis Thus on heating 1 per cent solutions in N/10 aqueous acetic acid at 100° C the three opalescent solutions quickly become more opalescent With *Bact typhi murium*/F68 and 901/F68 a precipitate quickly begins to form after five minutes in the first case and after ten minutes in the second, complete flocculation occurring within thirty to ninety minutes with the formation of a clear supernatant liquid of constant optical rotation, and the separation of a white flocculent precipitate With R R /F68, however, no obvious flocculation occurs even after heating the acetic acid solution for 12 hours From each of the three hydrolysis solutions a mixture of polysaccharides is obtained by precipitation with ethyl alcohol, and each of these mixtures contains as one of its constituents a highly dextro rotatory polysaccharide

Discussion

These observations, taken as a whole, offer certain suggestions in regard to the possible nature of the Vi antigen, and the factors that determine its immunological behaviour

It has been found that —

(*a*) The whole bacterial cells from a Vi strain of *Bact typhosum*, killed by the addition of formol and heating at 55° C, are a more effective immunising agent in the mouse than the whole bacterial cells derived from an O strain This difference is relative, not absolute It is most evident when the immunising injections are given by the subcutaneous route, and when they are not more than two in number When three injections are given intraperitoneally, the killed O bacilli induce an immunity of the same order as that induced by the killed Vi bacilli

(*b*) These results are exactly paralleled by purified antigens of the F68 type isolated from the Vi and from the O strain Our own experience and that of other workers make it extremely probable that these components represent the complex polysaccharide somatic antigens of typhoid or paratyphoid bacilli in their naturally occurring state

(*c*) Preliminary chemical studies have shown that the F68 antigen isolated from a Vi strain differs in certain of its chemical characters from the F68 antigen isolated from an O strain

These findings seem to admit of only two hypotheses Either the Vi antigen is a modified O antigen, or the Vi antigen, though a separate chemical entity, has chemical properties so similar to those of the O antigen that it remains associated with it throughout a long series of chemical fractionations Of these hypotheses, the first seems inherently the more probable It would be in no way surprising if the smooth somatic antigen of the typhoid bacillus developed, under certain conditions, relatively labile groupings of an immunologically active kind There is an obvious analogy in the acetyl polysaccharide of the Type I pneumococcus described by Avery and Goebel (1933) When fully developed these groupings might dominate the surface of the bacterial cells, so that these become irresponsive to the O agglutinins If the Vi groupings were partially developed the cells might be flocculable by both Vi and O agglutinins as we know the intermediate strains to be When the Vi groupings were very poorly developed or altogether absent the cells might be agglutinable only by an O antiserum The results that we have obtained with the O (901) strain clearly suggest the possibility that, even in this strain, the Vi groupings are not altogether absent

It would seem to us that this might be adopted as a tentative working hypothesis were it not difficult to reconcile with certain recent findings of Felix and Pitt (1935) These workers have described the isolation of a rough avirulent variant of a particular Vi strain of *Bact typhosum* which appears to have retained the Vi antigen while losing the smooth somatic antigen of the O type Of four rough variants of Vi strains described by these workers, two had lost both the O and Vi antigens, one had retained a proportion of both, and one had retained the Vi but had lost the O To fit these findings into the working hypothesis suggested above it would be necessary to assume that, in this particular variant, the Vi groupings had become relatively stable, or, in some other way, had come so to dominate the behaviour of the O Vi complex that the O groupings no longer exerted a significant effect, or, alternatively to assume that the complex polysaccharide antigen that is present in rough variants shares with the smooth O antigen the capacity for developing Vi groupings This problem clearly demands further study, but, at the moment, we feel that these observations by Felix and Pitt must be regarded as rendering less probable the working hypothesis that we should have been inclined to adopt on the basis of our own results

Finally, it appears possible to isolate from suitable strains of *Bact typhosum* a chemically pure and stable antigen that has the immunising properties of the whole bacterial cells

These studies, and others in the same general field, are, of necessity, extremely expensive They involve the growth of relatively enormous masses of pathogenic bacteria, laborious and large-scale chemical manipulations, and the annual expenditure of many thousands of money in the immunological assay of the various chemical fractions isolated They have been rendered possible by grants received from many different sources from the Leverhulme Trust, the Pilgrim Trust, Imperial Chemical Industries, and from a fund raised by Sir Austen Chamberlain, to which many generous private donors have contributed To all these we would express our thanks One of us (J W) is receiving a research grant from the Medical Research Council, one (S W C) is holding a Grocers research scholarship, and one (M S), while collaborating in this work, was holding a Beit memorial fellowship

WALSALL HEALTH SERVICES —A new infant welfare centre which cost £2600 to build, has been opened in Pool street Walsall In July a municipal midwifery service is to be established, and fourteen midwives will be appointed to the staff of the health department

THE IMMUNISING ACTIVITY OF CERTAIN CHEMICAL FRACTIONS ISOLATED FROM HÆMOLYTIC STREPTOCOCCI

BY T C STAMP
AND
E B HENDRY

(From the London School of Hygiene and Tropical Medicine)

SEVERAL attempts have recently been made by different workers to isolate immunologically active fractions from hæmolytic streptococci. Lancefield (1928 1933 1934) has shown that three or more distinct components may be extracted from the bacterial cells by means of HCl at a temperature of 100° C These substances were found to differ in their chemical nature and in their distribution among hæmolytic streptococci from different sources One of these components was shown to be a protein specific for each antigenic type as determined by agglutination and cross-protection tests In some strains the type-specific substance that was isolated proved to be a polysaccharide Another component isolated was found to be shared by a number of different types forming definite groups of hæmolytic streptococci. These group-specific substances had the properties of complex polysaccharides A third component described as a nucleoprotein was shown to be less specific the same antigenic substance being found in streptococci from widely different sources None of these fractions appeared to be fully antigenic though all were found to react in vitro to form characteristic precipitates with suitable antisera Fractions capable of producing antibodies when inoculated into animals have however been isolated by other methods Lancefield was able to isolate a non-specific nucleoprotein substance by extraction of the bacterial cells with saline in the cold. This was found to give rise to antibodies reacting with similar fractions from a wide variety of strains

Heidelberger and Kendall (1931 1936) have isolated by extraction with phosphate buffer solutions of different pH various protein fractions some of which were found to give rise to type and group specific antibodies Up to the present however no fractions isolated have been shown to be capable of inducing active immunity when inoculated into animals The object of the present work has been to investigate the possibility of isolating immunising fractions of this type from different strains of hæmolytic streptococci, with a view to studying their chemical composition

Experimental

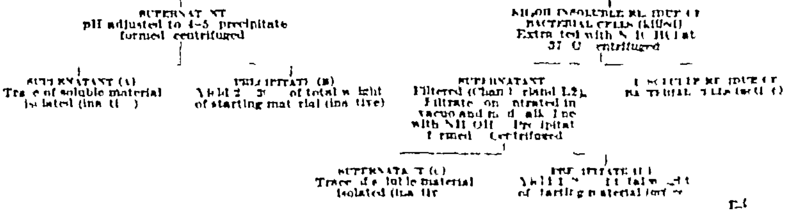
Fractions have been isolated from the dried or fresh living bacterial cells in various ways and tested for immunising potency by methods similar to those followed by Raistrick and Topley (1934) Groups of mice have been immunised with a standard preparation of dried bacterial cells and with different fractions to be tested over a period of three weeks The following method of immunisation has been found to give a satisfactory degree of immunity when the standard preparation was employed and has been adopted as a routine for all fractions During the first week each mouse received three doses of 0 1 mg of the fraction to be tested given intraperitoneally on three successive days followed by four days rest During the second week each dose was raised to 0 2 mg and to 0 3 mg during the third week Each animal received a total of 1 8 mg Seven days after the last immunising dose the groups of mice were tested for resistance to infection with the homologous strain the dose of washed living organisms administered intraperitoneally being sufficient to kill all non immunised control animals included in each test The mice have been kept under observation for 28 days and the potency of each fraction has been compared with that of the standard preparation by a comparison of the percentage of survivors in each group

THE FRACTIONATION OF A GROUP C STRAIN

Strain S34 has been used throughout the earlier part of the work for the preparation of fractions It had been isolated from bovine mastitis by Stableforth and was found to fall into Group C by Lancefield's group precipitin reaction resembling the animal strains of that group in fermenting sorbitol and not trehalose It has been found to be moderately virulent for mice having an average lethal dose of 10 000 organisms as estimated by colony counts The infecting dose employed has been about 100 average lethal doses or approximately one million organisms The material for fractionation has been prepared by growing the strain for 24 hours at 37 C in Hartley broth to which 0 5 per cent of glucose had been added centrifuging the deposit of growth and washing in distilled water In preparing the standard dried bacterial cells the washed living cells have been partially extracted with acetone at 37 C to kill, washed with alcohol and ether and dried off in vacuo over concentrated sulphuric acid This preparation has been found to be entirely non

TABLE I

Method of Isolation of HCl-soluble and NH_4OH-soluble Fractions of Strain S34 (Group C)



LIVING BACTERIAL CELLS
Extracted with N/10 NH4OH at 37° C centrifuged
SUPERNATANT
pH adjusted to 4-5 precipitate formed centrifuged
NH4OH INSOLUBLE RESIDUE OF BACTERIAL CELLS (killed)
Extracted with N/10 HCl at 37° C centrifuged
SUPERNATANT (A)
Trace of soluble material isolated (inactive)
PRECIPITATE (B)
Yield 2-3% of total weight of starting material (inactive)
SUPERNATANT
Filtered (Chamberland L2), Filtrate concentrated in vacuo and made alkaline with NH4OH Precipitate formed Centrifuged
INSOLUBLE RESIDUE OF BACTERIAL CELLS (killed)
SUPERNATANT (C)

isolated (not tested)
PRECIPITATE (C)
Yield 2–5 % of total weight
of starting material (active)

toxic for mice even when large doses were employed It was at first used as the starting material for the preparation of fractions, but later it was found that the fresh washed undried cells were more suitable for fractionation Attempts were at first made to isolate immunising fractions by methods similar to those employed by Raistrick and Topley in the case of *Bact aertrycke* (1934) It was found, however, that digestion with trypsin completely inactivated the standard preparation This method therefore had to be abandoned and an attempt was made to isolate an active fraction by extraction with dilute acids and alkalis The methods which have been employed are outlined in Table I It will be seen that the freshly grown bacterial cells of strain "S34" have first been extracted with N/10 NH_4OH at 37° C until no more NH_4OH-soluble material was removed The extract has then been centrifuged at high speed to get rid of all bacterial debris and the great bulk of the NH_4OH soluble material has been found to be precipitated on adjusting the reaction to between pH 4–5 This precipitate, called Fraction B, has been washed in absolute alcohol and ether, and dried off in vacuo over concentrated sulphuric acid The NH_4OH insoluble residue of bacterial cells has then been extracted completely with N/10 HCl at 37° C The acid extract after being passed through a bacterial filter (Chamberland L2) has been made alkaline with NH_4OH A white precipitate formed which was removed by centrifuging, washed and dried off as before This HCl-soluble NH_4OH-insoluble material called Fraction D, has been tested together with the NH_4OH-soluble Fraction B The results of immunisation with these two fractions are shown in Fig 1

It will be seen that the HCl-soluble NH_4OH-insoluble fraction showing 17 survivors out of 25, or 68 per cent after twenty eight days, has induced a degree of immunity equal to that produced by the standard preparation with 15 out of 25 survivors, or 60 per cent

The NH_4OH soluble Fraction B however, has proved completely inactive all 25 mice immunised with this fraction dying within forty eight hours The non immunised control mice were also all killed within a few days Further batches of the HCl soluble NH_4OH-insoluble fraction have been prepared and on testing have shown a similar degree of immunising activity It was found that the active acid-soluble material might also be isolated from the HCl extract by dialysis—the fraction settling out as a bulky precipitate within twelve hours Fractions prepared by this method did not appear as pure as those obtained by ammonia precipitation, which have the following properties The active fraction appears to be protein in nature, giving positive biuret and ninhydrin reactions It contains arginine, tyrosine, and tryptophane and is completely inactivated by tryptic digestion The Molisch reaction for sugars is negative, but after hydrolysis a small amount (about 6 per cent) of reducing substance calculated as glucose, can be detected The fraction is insoluble in distilled water and ammonia, but dissolves readily in acid to give a water clear solution. It is precipitated by one third saturation with ammonium sulphate It is not coagulated by boiling in very dilute acid The rotation and total nitrogen content are fairly constant in different batches of the fraction, and neither value was found to change during repeated reprecipitation by ammonia

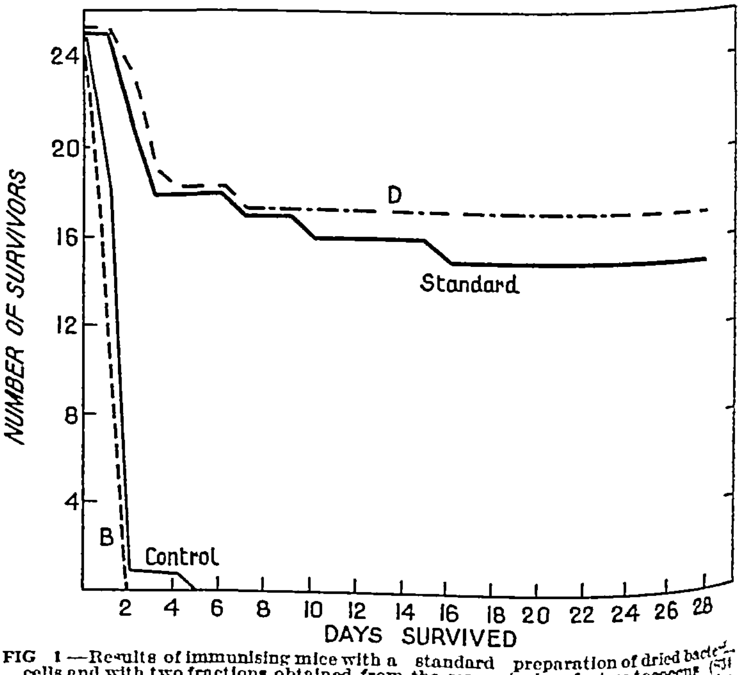

FIG 1 —Results of immunising mice with a standard preparation of dried bacterial cells and with two fractions obtained from the same strain of streptococcus (S34 Group C) The fractions are a NH_4OH soluble fraction (B) and a HCl-soluble NH_4OH insoluble fraction (D) The control mice were not immunised

from acid solution The average rotation value was found to be $[\alpha]_{6461}^{20} = -75°$ in N/10 HCl and the total nitrogen was 12 8 per cent The *fraction therefore appears so* far as can be ascertained at present to be practically homogeneous Since the arginine content is comparatively low (7 2 per cent) the protein would appear to fall into the histone rather than the protamine group

THE FRACTIONATION OF A GROUP A STRAIN

Following the isolation of an immunising fraction from a strain belonging to Group C an attempt was made to isolate a similar fraction *by the same methods from a* Group A strain Richards This had been isolated by Colebrook from a case of puerperal septicæmia and had been passaged through mice until highly virulent the average lethal dose being approximately 1000 organisms It has been shown *to belong to Griffith s Type 3 The infecting dose employed* has been about 100 000 organisms or 100 average lethal doses This strain was found to yield an HCl-soluble NH_4OH insoluble fraction when treated in the same way as ' S34 On testing this fraction it was found to be completely inactive Further tests showed that the activity of the *standard preparation* was destroyed by treatment with N/10 NH_4OH but remained unaltered by N/10 HCl It was therefore decided to extract the living cells directly with N/10 HCl as is shown in Table II When all acid-soluble material had been removed the extract was passed through a bacterial filter and neutralised being kept just acid to litmus A heavy precipitate formed which was removed This has been called Fraction A The clear supernatant was concentrated and dialysed to remove inorganic salts A further precipitate formed called Fraction C This was also removed by centrifuging The supernatant after dialysis appeared almost free from organic matter and was discarded The two precipitates were dried off and tested as before for immunising activity and the results are set out in Fig 2

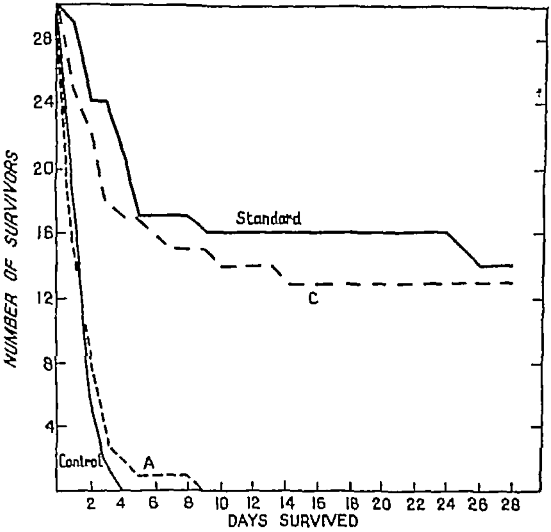

FIG 2.—Results of immunisation with the standard preparation and with two HCl-soluble fractions of strain Richards (Group A) Fraction A is a precipitate on neutralisation and Fraction C a precipitate on dialysis.

It will be seen that the precipitate forming on dialysis (Fraction C) showing 13 out of 30 or 43 3 per cent, survivors has produced a degree of immunity equal to that of the standard preparation with 14 out of 30 or 46 7 per cent survivors The precipitate formed on neutralisation of the extract (Fraction A) however has proved entirely inactive Further tests with different batches of the active fraction have also produced positive results though there is considerable evidence that the Richards active fraction is much more labile than that from S34 and rapidly loses its potency on keeping Attempts are now being made to fractionate this material further since it almost certainly contains some of the inactive Fraction A It is not possible to say to what extent the immunity induced by the active fractions of S34 and Richards is specific since cross *protection tests with these substances have not yet* been made That induced by the unfractionated cells however has been shown to be strictly type specific It is of interest to note that the antigenic components which induce an active immunity against hæmolytic streptococci belong to a different chemical category from those which induce an active immunity against bacilli of the typhoid paratyphoid group This finding is in accord with the results obtained by many other workers who have studied the in vitro reactions of these bacteria or of extracts derived *from* them and with the view that the component concerned in antibacterial immunity are those that dominate the surface of the bacterial cells in their virulent state

Summary

(1) Fractions capable of inducing active immunity in mice have been isolated from strains of hæmolytic streptococci belonging to Groups A and C

(2) The active fraction from the Group C strain is soluble in dilute acids but insoluble in ammonia and is probably a protein It appears to be comparatively stable and is not inactivated by ammonia

(3) The active fraction from the Group A strain resembles that from the Group C strain in being acid soluble but is inactivated by NH_4OH and loses its potency more readily on keeping It also appears to be protein in nature

Our thanks are due to Dr A. W Stableforth who kindly supplied the strain S34 and to Dr L. Colebrook for strain Richards One of us (I B H) is indebted to the Halley Stewart Trust for a personal grant The general expenses connected with the investigation have been met by the fund mentioned in the preceding paper

DIAGNOSIS AND TREATMENT OF DUODENAL ULCER *

By Fletcher McPhedran, M B Toronto
ASSISTANT PROFESSOR OF MEDICINE IN THE UNIVERSITY OF TORONTO AND

Trevor Owen, M B Toronto, M R C P Lond
SENIOR DEMONSTRATOR IN MEDICINE IN THE UNIVERSITY

(From the General Medical Clinic, Out patient Department, the Toronto General Hospital)

If we except arthritis in all its bizarre forms, there is probably no serious disease that can make a patient feel more miserable than duodenal ulcer It is very trying to be perpetually or periodically conscious of discomfort related to food If there is also pain, which is common, the sufferer loses his ability to concentrate on his work, conversely worry about his job is in our experience one of the main causes of exacerbations

In so far as danger is concerned, there are the three major complications, all of which demand surgery—namely, perforation, repeated hæmorrhage, and stenosis from scarring But in two and a half years we have had only one patient, that we can trace, who has had to submit himself to operation, and then for a stenosis

Duodenal ulcer is encountered especially in men made tense and irritable by the demands of environment and occupation. One sees, too, sensitive men of middle age They have been employed all their lives, often in one firm They see their less efficient fellows laid off, and perhaps they are on short-time themselves Meanwhile they have been buying on the instalment plan and now for the first time in their lives have financial worries They lie awake wondering when and how they will be able to make payments on the household articles that are almost their own Often the weak link of the chain of their health is the digestive system, and it may be that the overactivity of the brain produces abnormal circulatory or spasmodic conditions in the duodenum which rapidly lead on to ulcer They have no hobbies with which to occupy their spare time The radio and the movie are their only distraction They have never done anything constructive Their work has consisted only in the repeated small operations of a modern industrial plant They have not done anything to distinguish them among their fellow men They have never been renowned for growing the best roses in the neighbourhood They are not distinguished as home "handymen," with the joy of accomplishing good repairing or construction They neither golf or bowl

There is another class of patient who is particularly pathetic in that he has had reason to consider himself an efficient machine physically and intellectually He is the "go getter,' the salesman, who after his day of high pressure selling must make out, and mail to the firm his daily report—whose sales must each month exceed those of the corresponding month of the preceding year In this connexion it is interesting to note Cushing's reference to the diencephalon and its relation to ulcer It is easy to imagine that ulcer may possibly have a determining cause as remote from the site of the lesion as is the brain

SYMPTOMS

The essential symptom, in our experience, is the periodicity of gastro intestinal distress If the classical symptom of pain at 2 A.M is present, the ulcer has been of long standing We have observed too that bouts of constipation, periodic in character and occurring without any other gastro intestinal symptom, are of cardinal importance Indeed, one may say that this symptom points to ulcer unless there are some other signs to make the physician sure there is some other cause for this periodic distress Many of these patients have "dieted." They have been advised to avoid the rough foods that are known to irritate an ulcer, such as raw apples, radishes, coarse greens, and condiments Often they will have been told by friends to stop the use of meat and even eggs The only protein taken then is the utterly inadequate amount found in milk and soups

TREATMENT

We have found it advisable, at least in the early stages, not to order an X ray examination Why fix in the patient's mind that he has, or is suspected of having, an ulcer ? It is better at first to try the therapeutic test of dieting and to warn him, if relief follows, that he is likely to have an ulcer unless he follows the régime outlined for two years Early treatment will be successful if it is thorough but it must be followed conscientiously for at least that length of time We find that the emphasis laid on alkalis is not justified Years of experience in medical practice have brought no uniformity of opinion as to which alkali is the best, and there is no agreement about the results of their use They are the least important of the means at our disposal

Physicians in the past have paid great attention to the details of what the patient should eat but have not advised him enough as to when and how he should eat his food According to our experience it is necessary that he should have milk and biscuits often and regularly We attach the greatest possible importance to his taking half a glass of milk and a biscuit every two hours between rising and bed time This applies whether one of the simple meals here outlined has just been taken or not if, for example, he has drunk his milk and eaten his biscuit at 11 A M and at 12 he has had his noonday meal, he should still drink half a glass of milk and eat a biscuit at 1 o'clock We regard this frequent feeding as of cardinal importance For breakfast he should have a cereal with milk, soft boiled or poached eggs, bread and butter, and perhaps a little jam or honey For dinner, a milk soup, mashed or pureed vegetables, bread and butter, and a milk pudding For supper, a list like that of breakfast with stewed fruit added to it He should be told not to smoke, not to take alcohol or condiments Of these restrictions the avoidance of tobacco in any form is of paramount importance If progress is good, his diet is enlarged to the three main meals described below, with refreshments between each meal These extra foods must be taken at least fifteen minutes before the time at which he is habitually conscious of distress It will be noted that the whole plan is to anticipate and prevent discomfort from, or even consciousness of, his stomach. That is to say, if the distress usually occurs at 4 P M, milk and biscuits should be taken at 3 45

It is essential that the patient should have enough time after the midday meal for a rest of an hour The lathe hand, the professional man, the clerk, the stenographer all can take enough time off to take milk and biscuit between meals If he does not do well on this simple diet, we find it advisable to add an antacid with atropine A warning is necessary against over-dosage, but atropine is very important.

---

* Read before the Ontario Medical Association on May 31st 933 (see addendum at end of paper)

Constipation is often a major symptom. We advise going to stool regularly at exactly the same time adopting a proper squatting posture and exercising counter pressure with toilet paper between the coccyx and anus This prevents prolapse (thus making the defæcation easier) and perhaps stimulates the rectum to increased activities by exaggerating the contact pressure between its posterior and anterior walls

The patient should be instructed that if he does not follow the dietary instructions of frequent feeding for at least two years the ulcer may return He should also be warned that if he does abandon his diet the slightest symptom of indigestion should be followed by a prompt return to his régime. Far too often we find patients who have had news from friends of some miraculous alkali that was going to enable them to eat as seldom as they wished

The patient should come back in two weeks again after a month's interval and subsequently if the progress is satisfactory every three months for two years Warning should be given of the symptoms of the major complication of a perforation Hæmorrhage is certain to be noticed. The physician can assure himself of adequate observance of his orders by directing the patient to write down a typical day's menu. Often it will be found that the light nourishment ordered for mid morning and afternoon has been omitted. Emphasis should then again be laid upon this essential point Failure through such omission is not a medical failure It is the patient's failure to take advice It is dangerous in the extreme for it may cause continuance of the ulcer or a recurrence.

Most books and instructions have that quaint phrase avoid worry How should one not worry if one is persistently conscious of distress when there should be a feeling of well being? It is far better to advise the patient constructively as to how he can employ his spare time There may be twenty ways of remembering but there is no way of forgetting except by diversion He should have occupation in leisure hours, not laborious but pleasurable and if possible showing profits that will distinguish him from his fellows Gardening home carpentry making or doing jig saw puzzles or doing cross word puzzles or photography will so interest him that he will not worry Increased mental activity purposelessly applied—that is worry—makes the ulcer worse

DAILY RÉGIME

The following is our daily regime for these patients —

A glass of water slowly and then another

Breakfast —Apple sauce prunes or a ripe banana. Cooked cereal with top milk and wheat germ Boiled poached or coddled egg Toast and butter Tea or coffee with plenty of milk

Water-closet —At same time daily Position and pressure as described above

10 30 a m —Glass of milk or buttermilk and a biscuit

Dinner —Strained cream of vegetable soup or milk to drink No veal or pork but any roast boiled or broiled fish beef or lamb potato and another boiled vegetable mashed through a sieve and butter added Any milk pudding (custard, tapioca, bread pudding or blanc mange) jelly or stewed fruit bread and butter

Rest an hour

4.30 p.m —Glass of milk and a biscuit

Supper —Cream soup made with any of the above puréed vegetables or tomato juice or milk Any cold meat cheese fish or egg dish Stewed fruit with milk Toast or dried bread Milk in tea or coffee

10 p m —Glass of milk. Toast

Bed at 9 15 five nights a week. No smoking or drinking Dose of medicine after each meal

The powder is as follows —

Atropine sulphate	1/75 grain
Calcined magnesia	120 grains
Soda bicarbonate	120
Calcium carbonate	ad 480

½-teaspoonful after meals and as required. To be repeated Watch for atropine intoxication.

ADDENDUM

We have purposely refrained from publishing the above paper for several years, lest its optimism should prove unjustified We have been more than ever impressed however by the success of our efforts The points that we want to impress at this date are first of all, the need of being hopeful secondly the inadvisability of fixing the patient's attention upon a duodenal ulcer (as may be done by X ray examination) thirdly the necessity for frequent feeding and fourthly and most important of all, the importance of diversion if recurrences are to be avoided.

THE USE OF "DORYL" (CARBAMINOYLCHOLINE) IN POST-OPERATIVE AND POST-PARTUM RETENTION OF URINE *

By Chassar Moir M.D F R C S Edin F C O G

READER IN OBSTETRICS AND GYNÆCOLOGY IN THE UNIVERSITY OF LONDON AT THE BRITISH POST GRADUATE MEDICAL SCHOOL

The nervous control of the bladder musculature and the processes involved in the act of micturition are extremely complicated and still only in part understood It is certain however that much of the muscular activity of the bladder is under the control of the parasympathetic nervous system

As the result of the investigations made during recent years by Dale and Loewi and their associates it is now generally agreed that nerve impulse in the parasympathetic system is transmitted across synapse and passed from nerve ending to muscle or gland by the momentary liberation of a chemical substance acetylcholine which is itself almost instantly destroyed by enzyme action. Acetylcholine can be prepared synthetically and if administered in an appropriate manner it will reproduce the effects of parasympathetic stimulation. It has therefore been suggested that acetylcholine or an allied substance might be effective in promoting micturition in cases of post-operative retention of urine due to atony of the bladder wall or even to reflex spasm of the bladder sphincter

Since acetylcholine is rapidly destroyed by enzyme action in body fluids injection of even relatively large doses of this substance cannot be expected to produce more than a fleeting stimulation of the organ controlled by the parasympathetic nerves system On the other hand, certain other choline esters have a pharmacological activity approaching that of acetylcholine while being, at the same time, much more resistant to enzyme action One of these esters—carbaminoylcholine—has been issued to the medical profession under the trade name of Doryl. Among its suggested therapeutic uses is the treatment of retention of urine, and Schulze[1] has reported successful results in some 75 per cent of cases in which it was used after operation or after childbirth The Therapeutic Trials Committee of the Medical Research Council agreed to accept doryl for further clinical trial in this way, and the manufacturers (Messrs E Merck of Darmstadt) have kindly supplied it for the purposes of the tests described below

---

* A report to the Therapeutic Trials Committee of the Medical Research Council

DOSAGE OF DORYL

Doryl is issued in tablet form for use by mouth and also in ampoules containing 0 25 mg of the pure substance (carbaminoylcholine) dissolved in 1 c cm of fluid, the solution is intended for hypodermic or intramuscular injection In a few preliminary experiments oral administration of doryl proved ineffective in promoting micturition, and injection was therefore resorted to In the cases to be reported a full ampoule was used, and the dose was usually given intramuscularly

RESULTS IN CASES OF RETENTION OF URINE

In a preliminary series of some 10 cases of post operative retention of urine, injection of doryl was found to be remarkably successful in causing the patient to void urine within a few minutes, thus avoiding the necessity of catheterisation After this initial success, detailed records were kept of the effect of the drug in order to provide a report for the Therapeutic Trials Committee, and the present statistics refer to this later series of observations

The patients were unselected and consecutive cases of retention of urine occurring in the gynæcological and obstetric wards of Hammersmith Hospital (British Postgraduate Medical School) All the cases were those showing evidence of bladder distension of such degree as would, in ordinary circumstances, necessitate the use of a catheter The total number of cases collected is comparatively small (38), but it is intended that the results should be considered in conjunction with the similar report by Mr J S Maxwell, who tested the drug in the surgical unit of the Western General Hospital, Edinburgh The case records have been divided into three groups—successes, partial successes, and failures By a "partial success" is meant that the patient voided urine after administration of doryl, but that subsequent evidence showed the bladder still to be incompletely emptied.

Successes	14	Abdominal section	4
		Colporrhaphy	3
		Curettage	2
		Attempted abortion self injury	1
		Post partum	4
Partial successes	8	Colporrhaphy	1
		Post partum	7
Failures	16	Colporrhaphy	3
		Bartholin gland excision	1
		Post partum	12

In most of the cases one dose only of doryl was given but in 5 the dose was repeated Thus a patient who had voided urine satisfactorily after administration of doryl later had a recurrence of retention, this was again successfully treated by an injection of the drug Similarly, 3 patients listed as partial successes had a recurrence of retention and were again given doryl (twice in one case), the results were again partial successes One patient, who was suffering from over distension of the bladder, and who had failed to respond to the drug, was not relieved by its repeated administration

It was found that if doryl was to be effective, the patient usually felt a desire to micturate within 15 minutes of the injection Sometimes the effect appeared in as short a time as 5 minutes, and for that reason it was found to be important to give the patient a bed pan immediately after the administration of the drug It is fairly certain that some of the early failures were due to a lack of appreciation of this fact—the urge to micturate being allowed to subside before the patient was given facilities to void urine

COMMENTARY

Some of the successes were remarkable, and not infrequently the patient passed flatus or fæces in addition to voiding urine

It will be seen that most of the failures were in cases of post partum retention of urine Some of the patients in this group were suffering from injury to the vulva or perineum following difficult forceps delivery, and the compression of the urethra caused by the subsequent œdema and muscular spasm possibly explains the non success of the drug It seems likely, however, that a more common reason for its failure was a delay in the use of the drug until the bladder had become seriously over distended It is remarkable how often a puerperal patient has a symptomless yet gross over distension of the bladder It is also not uncommon to find that after apparently normal micturition such a patient will have a residual bladder content of 15 oz or more In some of the failures with doryl subsequent catheterisation showed that the bladder contained more than 30 oz of fluid This over distension is regrettable, yet it is notorious how often such a condition of the bladder escapes detection during labour and in the puerperium It is probable that had post partum retention of urine been detected at an earlier stage the doryl treatment would have been considerably more successful

As was to be expected, colpoperineorrhaphy caused in some cases a stubborn retention of urine the mechanical procedures involved in this operation not infrequently produce a compression of the urethra which only catheterisation can overcome

SIDE EFFECTS

The pulse rate was in each case taken before injection and again quarter of an hour after administration of doryl Usually it was unchanged Sometimes it was slightly accelerated In one case it dropped from 84 beats per minute to 60

In 8 cases the patient complained of nausea or faintness, or admitted to having these symptoms after direct questioning In one case the faintness was of some severity and led to anxiety on the part of the nursing staff, it lasted for a few minutes only Another patient who felt nauseated, actually vomited some minutes after the injection A few patients complained of salivation, and a few stated that they "felt hot all over"

In spite of the variety of possible side effects, one is left with the impression that injection of doryl in the recommended dosage seldom causes more than a minor disturbance, and in this connexion it must be remembered that there are many sensitive patients who are upset by the procedures involved in any hypodermic injection

THE POSSIBLE EFFECT OF SUGGESTION

It may be questioned by some whether the successful results recorded in this paper were not in fact due to the effect of suggestion on susceptible patients and were therefore unconnected with the specific action of the drug in reproducing the effects of parasympathetic stimulation. This criticism cannot be answered dogmatically but there is reason to believe that suggestion is not the chief reason for the successful result of the treatment. All the patients on whom the drug was used had already resisted the simpler methods usually adopted by the nursing staff to encourage a patient to pass urine Again the bladder evacuation usually coincided in time with the appearance of the side effects in those patients who showed such symptoms Finally the fact that a few patients not only micturated under the influence of doryl but also evacuated a substantial part of the content of the colon and rectum considerably strengthens the belief that the bladder effect is part of the specific pharmacological action of the drug

SUMMARY

1 A series of 38 cases is reported in which post operative or post-partum retention of urine was treated by injection of doryl (carbaminoylcholine)

2 Doryl is often remarkably successful in causing the patient to void urine naturally and is worthy of trial in patients for whom catheterisation would otherwise be necessary

3 Its most successful use is after abdominal section or after a simple vaginal operation It is least successful in patients suffering from over distension of the bladder—especially after childbirth and in cases in which there is mechanical obstruction to the passage of urine

4 One of the chief errors to guard against is the assumption that a patient has completely emptied her bladder by the micturition induced by the drug Often the evacuation is only partial

5 Side effects are seen in about a third of the cases, but are seldom serious

---

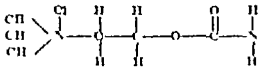
THE TREATMENT OF
POST OPERATIVE RETENTION OF URINE WITH DORYL *

By J S Maxwell, M.B Edin

LATE HOUSE SURGEON IN THE SURGICAL UNIT WESTERN GENERAL HOSPITAL, EDINBURGH

In recent months all cases of post-operative retention of urine in the surgical wards at the Western General Hospital Edinburgh have been treated by injections of Doryl solution

The makers (Messrs E Merck of Darmstadt) state that doryl is carbaminoylcholine chloride its formula being:—



Its actions are similar to those of acetylcholine but it is much more stable and is claimed to be effective even when given by mouth. It is issued as tablets containing 0 002 gramme doryl for oral administration and as an isotonic solution in ampoules for injection; the dosage suggested for subcutaneous or intramuscular injection is 0 00025 g doryl which is contained in 1 c.cm. of the solution

Through its influence on the parasympathetic nervous system doryl has been shown in pharmacological experiments to cause a decrease in heart rate a fall in blood pressure dilatation of the peripheral blood vessels and contraction of the muscle of the bladder and intestinal tract It is recommended by the manufacturers for the treatment of such diverse conditions as retention of urine intestinal atony hyperpiesia, paroxysmal tachycardia and eclampsia but the present investigation is concerned only with its action on the bladder muscle The antidote in cases of overdosage is atropine

INCIDENCE OF POST OPERATIVE RETENTION

During the time of the investigation 240 general surgical operations were performed at the hospital Post-operative retention of urine developed in 17 cases or 7 per cent. It did not occur in any patient *below the age of twenty years* between the ages of twenty and eighty the incidence was nearly uniform at all ages but the 14 patients over the age of eighty escaped this symptom The incidence in men was 7 7 per cent and in women 6 4 per cent

Excision of hæmorrhoids was the operation most often followed by retention of urine next came appendicectomy and other operations within the abdomen In the 30 patients operated upon for radical cure of inguinal or femoral herniæ there was no instance of post operative retention of urine

DOSAGE OF DORYL

If 24 hours after operation the patient was acutely distressed and could not pass urine 1 c cm of doryl was injected subcutaneously This dose was repeated at half hour intervals until the retention was relieved or until a total of 3 c cm had been given There was however no clear indication against reducing the interval between doses or of giving even more than 3 c cm (0 00075 g) subcutaneously Oral administration was not tried in this experiment

RESULTS

Of the seventeen patients treated with doryl eleven responded rapidly and passed urine within 5–25 minutes of the first injection Four others required three injections each passing urine within 15–30 minutes of the third dose The remaining two patients failed to micturate within 30 minutes of the third injection and might therefore be classed as failures both these however were relieved spontaneously within two hours In the successful cases in this series it appeared that doryl caused adequate emptying of the bladder and in all but two of them micturition thereafter proceeded normally Two patients had recurrences of retention one on the second and third days after operation and the other only on the second day the first of these had had an excision of hæmorrhoids and the other an intra abdominal operation [illegible] recurrence of retention responded within 5 20 minutes to a single injection of 1 c cm doryl.

Operations liable to interfere mechanically with the urethra had been performed in five of the seventeen cases in this series (excision of hæmorrhoids in four and colpoperineorrhaphy in one) in all five of these cases the retention responded to a single injection of 1 c cm doryl, though in one, as mentioned above, it recurred on the two subsequent days Since the use of doryl began, no case in these wards has been catheterised for post operative retention of urine

---

* A report to the Therapeutic Trials Committee of the Medical Research Council

Three cases of acute retention due to prostatic enlargement also responded to doryl, though others failed to do so It has been tried with success in retention due to periurethral abscess, pneumococcal meningitis, and in a case of severe and chronic atonicity of the bladder and colon in a girl aged 23

SIDE-EFFECTS

The most common side effect was sweating It was never very profuse A few patients complained of nausea and a feeling of weakness Sometimes the pulse rate was not affected, but more frequently there was a decrease of about 10 beats per minute fifteen minutes after injection The systolic blood pressure also fell, 10–30 mm Hg fifteen minutes after injection After one hour the blood pressure again became normal Flatus was passed in many cases

CONCLUSIONS

Doryl given by subcutaneous injection is a useful remedy for post operative retention of urine The results obtained in this series of cases appear to justify its trial in retention of urine due to any cause other than extreme mechanical obstruction

I am grateful to Sir David Wilkie, director of the surgical unit, Western General Hospital, Edinburgh, for permission to publish an account of this study I am also grateful to the manufacturers of doryl, who supplied the material through the Therapeutic Trials Committee

---

RIDER'S BONE

REPORT OF A CASE

BY A MOORE, M B Lond

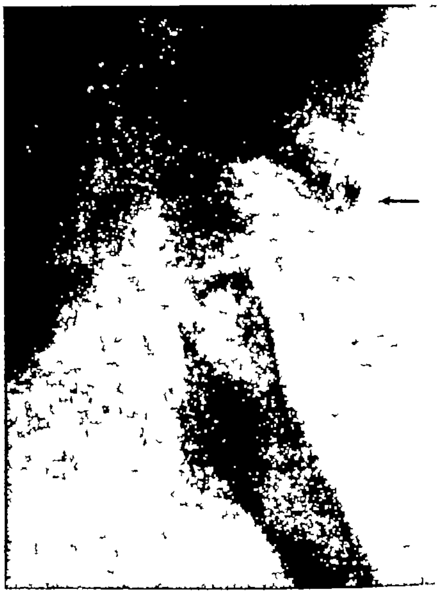
THERE is a tendency to regard the formation of "rider's bone" as a traumatic myositis ossificans

In the following case it seems likely that the tumour was originally caused by riding strains, for the lesion has the pathological structure of a traction exostosis

The patient was a man aged 38 Before the war he was a labourer used to horses but not to hard riding On joining the army he underwent intensive training and passed out as a rough riding bombardier He did not sustain any definite injury during these years of hard riding, and had no trouble until March, 1933 He had returned to labouring work, and while climbing a ladder he felt a sudden pain in his right groin, a loud crack was heard, not only by the patient but by two fellow labourers He was not incapacitated but felt pain and stiffness during the following week The same sequence of events occurred again in March, 1934, when he was running across a field, and he felt the pain and stiffness for five days No further trouble occurred until May 6th 1936, when he took part in a race A similar crack was heard, accompanied by sudden pain, on this occasion he was unable to walk and for the first time medical advice was sought

Examination revealed considerable limitation of flexion at the hip joint and on palpation a bony hard projection was felt between the anterior muscles of the thigh, there was much muscular wasting Radiography showed a mottled opacity continuous with the ilium, arising from the acetabular region and projecting down as a tongue-shaped process anterior to the right femur (see Figure) It was this tongue shaped process that was limiting the flexion of the femur, and it was simply to relieve the mechanical difficulty that Mr W B R Monteith decided to operate, as the patient was at that time completely incapacitated.

The *operation* was not intended to be an attempt at radical cure, but to improve the flexion of the femur and thus enable the man to return to work During the exploration it was discovered that the reflected head of the rectus femoris was taking origin from the distal extremity of the tumour As was suggested by the radiogram this originated from the ilium near the acetabulum The stalactite like projection was successfully removed, and since the wound healed the hip movements have been almost perfect Considering that he has been in continuous employment from that time, and that there are no signs of recurrence of disability, the procedure seems justified If any more radical measures are indicated later, further operation can still be undertaken



Radiogram showing the stalactite-like tumour at the origin of the rectus femoris

Histological report "The tumour is a traumatic osteoma, and has followed the avulsion of a portion of the periosteum due to muscular action There is subperiosteal hæmorrhage and presently organisation, and on the top of that calcification and ossification The section shows, of course, more or less irregularly formed bone with considerable vascularity and many wide intertrabecular spaces, along with areas of osteoid tissue"

In discussing the ætiology of ectopic bone the following theories must first be considered

Embryonic rests were held responsible by Cohnheim. When there is a definite history of muscle strain injury, and direct relation of tumour to periosteum this theory will hardly suffice, though it may explain cases where bone forms in the body of a muscle

Aberrant sesamoids are not usually found in the site common for tumour formation

Inflammation was considered by Grawitz and Salmon to be important but there is rarely any sign of inflammatory reaction with pyrexia When pyrexia follows injury and hæmatoma, bone formation is not invariable

Metaplasia was regarded as the cause by Reichert and others the connective tissue of muscles, fascia, tendons and ligaments being interchangeable and muscle taking on the powers of periosteum The theory seems very complicated and there is no histological proof

Hæmatomata have been considered by some as the primary cause of tumour formation blood corpuscles forming connective tissue and then bone Objection may be raised as in the last theory and neither explain cases in which there is a definite relation between tumour and periosteum

A congenital bone forming diathesis (Virchow) must be considered seriously since muscular injury with subsequent hæmatoma formation is not necessarily followed by bone tumours There must be some constitutional idiosyncrasy

Periosteal theory in which either injury to the periosteum with muscle crushed to pulp is followed by the escape of osteoblasts into the muscle pulp where bone may form or muscle-fibres are torn from their origin with periosteal cells or flakes of bone attached, with a similar result

The animal experiments of Davis and Hunnicutt (1915) are of great interest The results were briefly as follows —

1 Pedunculated transplants in muscle never formed bone

2. Pedunculated flap of periosteum alone never formed bone

3 Free periosteal flaps or pedunculated flaps with bone fragments attached always led to bone formation

In other experiments on animals detachment of individual muscle fibres from their origin by electrical stimulation has led to intramuscular bone formation from detached periosteum with bone fragments.

Although there was no definite history of injury I suggest that the cause of the tumour was the frequently repeated strains of the rectus femoris at its origin, when the man was forced to take up unaccustomed rough riding This sudden violent exercise did not first give a chance for agonistic and antagonistic muscles to become properly balanced as in more gradual training As a result of repeated slight muscle strains of the rectus fragments of periosteum with probably small flakes of bone attached were torn off by muscle fibres and the freed osteoblasts formed bone at the site By repetition of this process a tumour developed with the reflected head of the rectus apparently taking origin from its distal extremity This gave the appearance of a traction tumour Should this theory be true it seems that it is essential for all men embarking on similar unaccustomed violent exercise to have special preliminary training with exercises designed to develop gradually the particular muscle balance required It may be that a fair proportion of men possess the bone forming diathesis of which Virchow wrote

CLINICAL AND LABORATORY NOTES

DERMATITIS PROBABLY DUE TO MOTOR FUMES

By Arthur Whitfield M.D F R C P Lond.

CONSULTING PHYSICIAN TO THE SKIN DEPARTMENT KING'S COLLEGE HOSPITAL, LONDON

The following case appears to me to be worth recording on account of the difficulty often experienced in tracing the cause of acute outbreaks of dermatitis of the face I have not come across such a case either in my own experience or in my reading of that of others

The patient was a married lady of early middle age who had suffered for many years from urticaria and according to her statement every doctor who had tried to cure it had always made it worse All aperients made it worse and aspirin made her "swell up like a balloon It was also aggravated by oranges but not by grape-fruit Owing to her unfortunate experience with previous treatment she refused to allow me to attempt to cure her urticaria which she said she thought was very slowly dying out

About Christmastime 1934 she drove in a motor-car in the West of England in bleak weather Next day her trouble began with a stabbing tickle" at the top of the left eye and from this it spread until both eyes were sore and swollen and her face scarlet This she not unnaturally attributed to draught She consulted a specialist about it and he gave her a pot of scented cream but no prescription I made a rough examination of this cream; it appeared to me to be of the nature of a vanishing cream and I found that it contained soap At any rate its effect was disastrous as it inflamed her face badly just as it was beginning to recover On leaving off the application and using lead and milk lotion the skin resumed its normal appearance

Later she drove her own car down to see her boy at school and as it was cold weather she had all the windows up Two days later her whole face was again swollen and inflamed.

In February 1936 she consulted me about her face I realised at once that the case was a difficult one and was not inclined to accept the draught as a cause more especially after I had elicited the fact that she had recently stood some time on her doorstep in a cold wind without experiencing any relapse Noting that the windows of her car had been closed on each occasion which had preceded an attack I wondered whether there could be a possibility of fumes in the car as an exciting cause I therefore tried to persuade her to drive with the windows wide open—not a pleasant thing to do in cold weather She was driven by her husband but finding it too cold with the window wide open she closed it all but a crack at the top Next day she had another attack. She then followed my advice and drove some distance in cold weather and reported when I have driven the car since I have had the windows right down I am all over aches and pains but my face is all right"

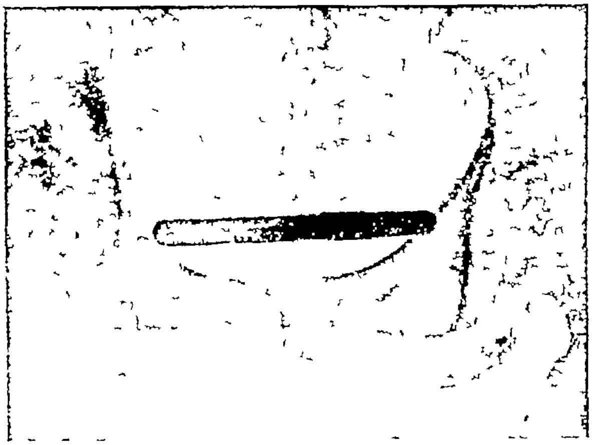
I saw this lady on Jan. 4th this year she has had no further attacks since the last experiment with the closed car nearly two years ago Her urticaria which was spontaneously improving when I saw her has disappeared That her dermatitis was not due to a peculiarity present in one car is proved by the fact that she had the eruption if she drove her other car with the windows closed The repeated experiment of driving in open and closed cars in cold weather is I think as nearly as possible proof that the eruption was caused by fumes in the closed car Owing to the extremely small doses which may affect sensitive patients I deemed it impossible to track down the exact constituent that was responsible but I rather suspect acrolein from partial combustion of the lubricating oil.

When I first saw her I persuaded her to take some glycerin of pepsin and hydrochloric acid with her meal This had an extremely beneficial effect on her urticaria and may have helped to desensitise her and so assist in the cure of the dermatitis On this point I should not like to offer a positive opinion

FOREIGN BODY IN THE BLADDER

BY DESBOROUGH BRODIE, M B, B S Lond.
HON SURGEON TO THE SHEPTON MALLET DISTRICT HOSPITAL

ON June 8th an old lady, aged 78, was doing needle work in bed She lost a clinical thermometer case containing four bodkins In getting out of bed to find it, she was conscious that something had entered her body On July 10th, over a month after the occurrence, she consulted me and was radiographed (see Figure) The case could be felt through the anterior wall of the vagina A suprapubic cystotomy was done and I extracted the case and bodkins Considering the difficulty so often found in introducing a catheter into the female urethra, this accident must be very rare There was no sign of cystitis



Radiogram showing position of thermometer case containing bodkins

---

ACUTE RETROGRADE JEJUNOGASTRIC INTUSSUSCEPTION

BY J M GREENWOOD, M.D Manch.
DEPUTY MEDICAL SUPERINTENDENT OF THE WITHINGTON HOSPITAL, MANCHESTER

ACUTE retrograde jejunogastric intussusception was first described in 1917 and less than 40 cases appear to have been recorded since (Adams 1935, Cameron and Macfarlane Pennyfather, Becker 1936) It arises at any time after the operation of posterior gastrojejunostomy and is usually diagnosed primarily either as an acute intestinal obstruction, or a hæmatemesis from a gastric ulcer According to Maingot (1936), when a hæmatemesis occurs after a gastrojejunostomy, one should always think of intussusception, and further, that in a patient with acute intestinal obstruction a diagnosis of retrograde intussusception should be made if the following three signs are present (1) an epigastric scar, (2) visible peristalsis with the waves passing from left to right, (3) a palpable mobile swelling about the mid abdomen.

A male patient aged 47, was admitted on Dec 28th 1936 with a diagnosis of hæmatemesis, possibly from a gastric ulcer He stated that he had had an operation for duodenal ulcer in 1928, and that he had been free from symptoms from that time, as long as he kept to his diet He said that he had had some indigestion recently, but denied any excess over Christmas There was a history of vomiting one pint of blood before admission.

On examination the patient was pale and emaciated but his pulse was regular and had a rate of 70 per min., his temperature was 97° F, and his respirations 20 per min The heart and lungs appeared normal, and the liver and spleen were not felt A mass was found in the epigastrium, and a provisional diagnosis was made of hæmatemesis from gastric carcinoma or ulcer Later, on the same day, the patient vomited 18 oz, and again 22 oz. of dark fluid which was considered to be blood The pulse rate shortly after this was 72, and morphine, saline, and heat were administered On Dec. 29th and 30th melæna stools were present and further attacks of vomiting occurred His pulse rate was usually between 70 and 80 but on one occasion rose to 108 A blood count was as follows red cells, 4,230,000, hæmoglobin, 70 per cent, colour index, 0 83 On the morning of Dec. 31st he again vomited more dark fluid but without any increase in pulse rate, and he said he felt better than on admission He had a further vomit of fæcal odour later in the day At this time he had no abdominal pain, he had had a normal stool and had passed flatus shortly before, he had a moist tongue and a pulse rate of 76 In the abdomen there was an upper right paramedian incision from the previous operation There was no abdominal distension, but the outline of the stomach could be seen, which on palpation was found to be of elastic consistency, not fixed, and not tender No peristalsis was visible and there were no glands palpable in the supraclavicular region. Mr A H Southam was asked to see the patient, and operation was decided upon, with the diagnosis of an upper intestinal obstruction

A general anæsthetic was given, and while in the anæsthetic room the patient passed both fæces and flatus per rectum A stomach tube did not relieve the distended stomach

On opening the abdomen the stomach was found to be enormously distended and the small intestine collapsed and the condition was recognised as one of retrograde intussusception The site of the gastro intestinal anastomosis was examined and the efferent loop of bowel was found to be intussuscepted The intussusception could not be reduced without opening the stomach, the mucous membrane of the intestine was congested and had a few gangrenous patches on its surface The intussusception was reduced with difficulty, and the length of bowel invaginated was estimated at 18–24 in The peritoneal aspect of the gut was good and the gut was considered viable The stomach and abdomen were closed and a continuous drip saline was instituted, but the patient showed signs of heart failure and died 3 days later on Jan 2nd

There seems to be two points of interest in the history First, a mass in the epigastrium of an emaciated man, aged 47, associated with hæmatemesis, was diagnosed as ? carcinoma of the stomach It was later diagnosed as a high intestinal obstruction, but if one had been familiar with the description of acute retrograde jejunogastric intussusception, a correct diagnosis might have been made Secondly, apart from the fæcal odour of the vomit there were no other signs of intestinal obstruction. The pulse rate at the time of the operation was 76, and fæces and flatus were passed in the anæsthetic room, presumably three days after the onset of the intussusception

My thanks are due to Dr M Gamble, medical superintendent of the Withington Hospital, and to Mr A. H. Southam for their permission to publish this case

MEDICAL SOCIETIES

MEDICAL SOCIETY OF LONDON

AT a meeting of this society held on Jan. 25th the president, Sir WILLIAM WILLCOX, being in the chair a discussion on the

Value of Experimental and Laboratory Training in Medical Education

was opened by Dr JOHN BEATTIE (Conservator of the Hunterian Museum). Laboratory training he said was essentially a training in experimental methods whether they were used in purely scientific work or for obtaining information of value in the diagnosis and treatment of disease. There was no real distinction between it and experimental training except in so far as the latter aimed at the inculcation of what was termed the experimental method whereas laboratory training was a training in technique and the use of methods. The results obtained from these manipulations were valueless unless those applying the results had a full appreciation of the value and limitations of the scientific or experimental method. The educational value to the medical student of his training in the experimental method was something apart from its factual content. John Hunter said to Jenner Do not think, try. Claude Bernard said Think, observe, try and think. Thomas Huxley said that the scientific method was trained and organised common sense. It could therefore be summarised as trained observation and trained thinking. Laboratory work trained the student to use methods which ensured accuracy of observation under known conditions. A distinction must be drawn between the intrinsic value of the subject matter of a science, and the educational value of that science. The method he was advocating engendered a healthy distrust of statements made on authority without apparent or provable evidence. In no field was such criticism more needed and less used than in medicine.

Medical education now commenced—unfortunately in Dr Beattie's view—in our secondary and public schools where chemistry and physics were taught successfully it might be from the point of view of examination but often with great damage to education in the experimental method. The deduction of a natural law from observed facts was of much greater value to the student than his knowledge that the volume of a gas varied inversely with its pressure. This brought him to the problem of the teacher. On arriving at a medical school it was very likely that the student did not know how to learn and even more likely that he did not know how to think. Yet in his first two years he was presented with a cold douche of facts which chilled his enthusiasm and gave him little chance to think. Too often when told to draw what he saw on a slide under the microscope a student would include something which was not there but which his text book led him to expect would be there. Good teaching would make sure that careful observation was gradually developing along with a critical sense. In anatomy schools too often students were lectured to in such a way that curiosity and enquiry were stifled. With the wealth of material in anatomical laboratories it ought to be and indeed was possible to lead the student away from considering that the final examination was the ultimate object of his course and to train him in manipulative technique accurate observation and logical deduction.

About the value of a scientific training in medicine there were two diametrically opposed points of view. Oliver Wendell Holmes said that, if a man had not plenty of good common sense the more science he had the worse it was for his patients. The other view could be summed up by saying that the most important difference between the practical doctor and the truly scientific one was that the patients of the former were more likely to die. In his own view the success of a doctor's education depended entirely on the emphasis which had been laid on the method and spirit of science. The methods of the diagnostician were essentially those used in procuring scientific data: accurate observation and experiment with logical deduction. The observations were made first by the unaided senses and then with instruments of precision and various laboratory procedures. From the educational point of view there was no difference between these and the experimental method used by the student in his laboratory unit. The data thus obtained when properly correlated and analysed according to the rules of the experimental method led to a conclusion as scientific as those of the investigator in a physiological laboratory. Many clinicians who continually insisted on the value of experience failed to realise in teaching that the medical student should obtain his knowledge for himself. There were profound differences in the training of medical students here and in America. In America the training in the medical sciences aimed specifically at inculcating the scientific method and ensured that there was no overloading of the student by masses of factual data. The student reached hospital eager and keen to carry on his clinical work in the same spirit. But in the ward the whole atmosphere seemed to have changed as he seemed not to be trusted to do anything. Too frequently he was not only told to listen to a heart but also what he would hear. In the English schools the position was reversed the routine laboratory courses seemed designed to crush out the student's desire to find things out for himself. Minot once said it was a disgrace to a university to appoint a man as professor chiefly because he was a good teacher; only investigators could give university instruction. On reaching the hospital ward the English student had the advantage over the American student that he was made to realise he must obtain his data for himself and draw his own deductions. That being so the value of the experimental method in teaching could not be denied. To state that the main purpose of medical schools was to turn out efficient practitioners was only another way of stating that they must be expert scientific investigators.

Prof JOHN RYLE (Cambridge) asked how far time could be allowed in the student's curriculum for the claims of the laboratory sciences. It was profitable to review the relative merits of laboratory and observational or bedside training especially as the merits might seem to vary with the ultimate destiny of the individual student. Some thought that in this matter a parting of the ways had been reached and that two curricula might be devised one for the man who wished to be a practising doctor the other for the medical scientist the laboratory worker. It was now customary for medical students to do their preliminary scientific work at school which meant that from the age of 16 or thereabouts they were specialising in chemistry physics and biology. Often unfortunately these were years of cramming rather than of training. The time available and the requirements of examining bodies also rendered a genuine experimental training impracticable at this stage The students were given a certain number of facts about crayfish and dogfish, and they learned them to pass examinations, but that was not a proper introduction to the observational or experimental method For a further three years, in the case of Oxford and Cambridge, they were concerned with anatomy, morbid histology, physiology, and an introduction to biochemistry, and perhaps general pathology In other words, four years at least were devoted to laboratory studies before there was any contact with a patient or a clinical problem Though valuable and necessary ground work was covered, these years involved so much instruction and accumulation of information by book and class and lecture that little time was left for thinking or argument, personal experiment, or a philosophical appraisement of experimental methods Although improvement had been attempted of late no concerted effort was made as a rule to bring home the essential unities of physiology and pathology, or the solid contribution which those two subjects could make to the study of man in health and disease

There was however a larger criticism of this earlier part of the curriculum, and that was that it did nothing to encourage unprompted observation or individual initiative in the perception and solution of naturally occurring problems A young man blessed with the instincts and hobbies of a naturalist and the important faculty of inquisitiveness might survive this type of training, and even derive new advantage from it, but such young men were exceptional The majority were decidedly unobservant, and the longer their training as observational scientists (naturalists or clinicians) was postponed the harder they would find it to acquire the necessary aptitude Moreover, since their scientific education had started early to the exclusion of Latin, literature, and logic, most of them had no compensatory qualities in the shape of humane understanding or powers of language and expression Among the best and sanest doctors in the world must be included a familiar type of Scotsman—a breed blessed with common sense and generally with a very sound general education In contrast, it was no rarity to find a student with a distinguished scientific record shaping very poorly in diagnosis, very slow in the development of clinical sense, and very clumsy and irrational in his therapeutic suggestions Unfortunately his disability tended to make him discontented with, or even contemptuous of, clinical methods Most good biologists, on the other hand, had been capable both in the observational and the experimental field, and whatever our goal, were we not all students of human biology? The aim surely should be to see how the laboratory approach and the clinical approach to medicine could be planned to run a parallel course The chief necessity was to keep human physiology in the foreground

In deciding whether separate curricula for scientist and practitioner were desirable it was necessary to ask whether the present curriculum included less than the scientist required, or more than the practitioner required Prof Ryle's own belief was that the honours schools of the older universities and the second M B of London provided an adequate standard for the intending scientist, and he was doubtful whether the standard could be lowered for the intending practitioner For both, however, the actual bulk of the subjects taken could be reduced A greater selection of subjects should, he thought, be sanctioned within the framework of physiology and anatomy so as to allow of a more intelligent study and lessen the necessity for cramming With this choice of subject there should be a choice of question in the examination The average student and intending doctor might for example concentrate more on a group including the cardiovascular system, the digestive tract, and the central nervous system, while the intending biochemist might concentrate on biochemistry, metabolism, and respiration But how often did a man know at this early stage what he wanted to do later? This was the strongest argument against a bifid curriculum It was as important for the scientist to receive the broad stimulus of the ward as it was for the clinician to be well grounded in the ancillary sciences And in the preclinical period nothing stimulated the student so much as a judicious attempt to illustrate his anatomical physiological and pathological studies with clinical material

DISCUSSION

Prof GREY TURNER spoke of the need to inculcate the grammar of the scientific method at the outset of the student's career It was not so much a matter of what was to be learned from the application of scientific methods as how to apply those methods, so that when the student came into contact with the problems he would know better how to approach them Therefore, even before the student came into contact with patients, he should be made familiar with the best methods for elucidating the problems of disease Students should learn that research was not necessarily finding out something new, but discovering something for themselves The scope of the medical curriculum was largely a question of balance, the fact that there were many types of students he thought was mainly due to differences of environment Too much latitude should not be given to a student's bias

Dr R A YOUNG would have it realised that medical education was only one aspect of general education. He had always tried himself to inculcate the inquiring, not necessarily the sceptical, attitude of mind. The student should be told that because a statement was made with a certain amount of authority it was not necessarily true, all great advances had been made by questioning what had previously been accepted. He remembered the time when the medical man who wanted to work in a laboratory had to do so by stealth, fearing lest being scientific he would not be sufficiently practical. He would like to see the word "research" in medicine replaced by "investigation" Medicine, as a science, should be looked upon as a branch of biology

Dr C M WILSON (Dean, St Mary's Hospital Medical School) suggested that a false antithesis has grown up between the clinician and the man of science A man of science was not one who used certain instruments in certain places, the paraphernalia of a laboratory were devices to make observations easier and more accurate than they would be if we depended on our unaided senses But we did not become scientists by using instruments to sharpen observation, it was a man's mental processes that made him a scientist Such a man was committed by the way he was made and by his training to a critical scrutiny of facts He was cautious and guarded, he had put aside prejudices and preconceptions It was this attitude of mind which it was the first duty of a medical school to foster Laboratory training helped us to this end because it was primarily a place where tentative hypotheses were put to the test A man working in a laboratory soon became conscious of the superiority of a statement that could be proved or had been proved over one that he had to take on the authority of his teacher He was initiated into the nature of evidence and nothing in the practice of our calling was quite so important to him as that

Lieut Colonel A H **Proctor** (Dean British Post graduate Medical School) felt that the medical student of to day got very little training in the experimental method He was usually given the explanation long before he started doing the experiment himself he was not told what was the problem he was faced with nor how to think about it. Provided the student had the right teachers his clinical work might start earlier than at present

Dr **John Freeman** contended that pure science was not the aggregation of data but an attitude of mind scientific education was education in a state of mind Students destined for general practice were filled up with many facts they were never likely to need Yet he did not know how examiners were to be prevented from asking foolish questions

Dr G W **Goodhart** stated his objection to having two separate curricula according to the kind of work the student wished ultimately to follow When he entered upon laboratory work himself he was given to understand that he must give up any idea of clinical medicine otherwise he could not claim to be a pathologist He lamented the fact that so few students knew how to use a clinical laboratory

Dr **Lionel Whitby** insisted that every doctor must have a fundamental basis of fact before he could attempt to work as an experimentalist Some thought the student had too much laboratory training and too little chance of observation in the wards but just as the pace of an army was that of the slowest soldier so the teaching of a class had to be regulated by the capacity of the dullest.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

At a recent meeting of this society held in Liverpool with Dr **Ruth Nicholson**, the president in the chair a paper on

Ruptured Uterus

was read by Dr D C **Racker** (Manchester) who described three cases treated at St. Mary s Hospital Manchester by supravaginal hysterectomy combined with blood transfusion and gum saline infusion by continuous drip In one case the patient had been in the hospital since just before labour began the diagnosis was made immediately after rupture and Dr Racker at once performed hysterectomy In the two other cases the uterus had ruptured before admission and one patient was almost moribund on arrival after a long journey In none of the three had there been a previous Cæsarean section but all had had difficult deliveries previously Two of the patients recovered completely but the third who had been so ill on admission died eight hours after operation. The anæsthetic used was nitrous oxide and oxygen in one case morphia and local (Novutox) in another and ether in the third

It appeared said Dr Racker that rupture of the uterus was becoming not less but more common than it was thirty years ago The increase could not be attributed to the greater frequency of Cæsarean section for the figures for rupture through an apparently normal uterus were not diminishing In these cases he thought there had probably been some previous trauma to the uterus even a partial or incomplete tear which had passed unnoticed and he therefore emphasised the importance of a thorough intrauterine examination after all difficult instrumental or manipulative deliveries In treatment he felt sure that the method of choice was supravaginal hysterectomy except possibly in cases with small incomplete tears Where a Cæsarean scar had ruptured it might be best to quickly suture the torn edges but sterilisation must follow later for no patient who had had a ruptured uterus should be allowed to become pregnant again Treatment per vaginam had no place whatever apart from small incomplete tears and intra uterine tamponage had always given extremely poor results. If the presenting part was low the temptation was to extract the child and operate later but this temptation should be resisted for the extraction might increase the hæmorrhage alarmingly bring down intestine or other viscera enlarge the tear and greatly lengthen the time before operation could be carried out. Formerly rupture of the uterus was nearly always fatal but with the introduction of hysterectomy in its treatment about 1900 the fatality rate suddenly decreased Even now however it was still alarmingly high about 25–40 per cent. in various clinics The prognosis depended on the interval between the accident and operation and on the amount of bleeding—i e. whether the placental side had suffered or a large vessel had been torn. Provided there were no vaginal manipulations the bleeding was often surprisingly slight even where the fœtus was lying free in the abdominal cavity A third factor—perhaps the most important—was sepsis Most patients had a somewhat stormy convalescence but with suitable treatment they should be discharged in a healthy condition

Mr A A. **Gemmell** described a case he had lately attended in which a woman was admitted to hospital after failed forceps and it was found necessary to perform Cæsarean section After removal of the child a vertical tear was found in the posterior wall of the uterus This was sutured and the patient recovered

Dr **Rhoda Adamson** (Leeds) maintained that trauma at a previous confinement was not a necessary ætiological factor She recalled a case of an 8 para who had had easy confinements yet ruptured her uterus during the first stage of labour as a result of turning suddenly from her back on to her side She died within ten minutes and post mortem a large uterine tear was found —Dr J W [illegible] (Manchester) referred to a case of rupture in which the uterus was infantile in type —Dr E A Gerrard (Manchester) supported Dr Racker contention that previous trauma is an important cause He pointed out that spontaneous rupture in a primigravida is rare

Obstructed Labour

Mr T N A **Jeffcoate** (Liverpool) reported the case of a woman aged 20 who was first seen at the 30th week of her sixth pregnancy She had had one previous abortion and four previous labours of the latter the first three had been normal but the fourth in 1932 was difficult and necessitated forceps delivery

When she was first seen her general health appeared excellent but on routine antenatal examination a cystic swelling was found behind and slightly to the left of the uterus. Its exact limits and size were difficult to define but there seemed to be no doubt that it was an ovarian cyst which was below the presenting part almost certain to obstruct labour The previous history of labours increasing in difficulty supported

She was admitted to hospital and allowed to go into labour spontaneously on June 30th, 1934 After she had been in labour eight hours, the cervix was two fingers' dilated, the membranes had ruptured, and the head was high above the cystic swelling Lower segment Cæsarean section was performed under general anæsthesia, and a living female child weighing 7 lb 4 oz was delivered When the uterus had been sutured the pelvis and abdomen were explored, and the operator was horrified to find no tumour The uterus, in fact, was unicornuate and there was no appendage on the left side A little thickening beside the pelvic colon was noted, but nothing to account for obstructed labour The placenta had been situated rather low down on the left wall of the uterus, and it was concluded that the sensation of a cystic swelling must have been produced either by the placenta or by a sacculation of the malformed uterus The puerperium was uneventful except for mild pyelitis associated with a slight rise of temperature on the fourth to ninth days This responded quickly to treatment with alkalis Careful bimanual examination a month after operation revealed no abnormal physical signs, and Mr Jeffcoate failed to excuse himself on any grounds for what he thought to be a gross error in diagnosis

The patient was next seen in October, 1935, when she was pregnant again (last menstrual period May 19th) The uterus was enlarged to the size of an eighteen weeks' pregnancy, and no unusual physical signs could be found on *vaginal examination* However, she was observed closely and with great interest, and examined repeatedly At the 30th to 32nd week of pregnancy the "tumour" again made its appearance, and it became more obvious as pregnancy advanced The case was discussed with a number of colleagues, and they one and all agreed that the correct treatment was to institute trial labour again, but they were unable to suggest the pathological nature of the condition At the 35th week the presenting head was high, and pus and albumin appeared in the urine This onset of urinary infection was not surprising in view of her previous attack of pyelitis in the puerperium and the well-known likelihood of its recurrence She was admitted to hospital for treatment but was fairly well except for occasional headache, a slight rise in blood pressure (150/80), and a little œdema She received treatment with urinary antiseptics, low protein diet, &c, but the albuminuria and pyuria persisted to some extent until the onset of labour

Labour began on March 14th, 1936, and after twelve hours the cervix was three fingers' dilated and drawn up, the membranes having ruptured, the presenting head was above a very obvious cystic swelling The patient's temperature then suddenly rose to 100 6° F, and her pulse rate became rapid (118) Dr A A. Gemmell saw the patient at this time, and agreed that Cæsarean section must be done

A lower segment operation was performed under spinal anæsthesia However, instead of opening the uterus before exploring the pelvis—as on the first occasion—a hand was passed down to the left of the head, and a very obvious retroperitoneal tumour was discovered about the size of a Jaffa orange A living male child (6 lb 2 oz) was delivered by the usual technique, and, having sutured the uterus, the operator proceeded to investigate the tumour more fully To his surprise it had once again disappeared However, on very careful palpation an indefinite soft mass—partly fluctuant—was discovered running down beside the pelvic colon He realised the risk of hæmorrhage in attempting to deal with pelvic tumours at the time of Cæsarean section, but in view of the temperature decided that further exploration was necessary There was no true broad ligament on the left side, but the peritoneum was incised and dissection carried out by finger only When the tumour was reached it was easily separated from its connexions Just before its removal was complete it burst and very offensive yellowish fluid escaped Care was taken to avoid clamping or cutting, since it was obvious the ureter must be very close At one stage a strand of tissue appeared, and in view of the possibility of its being the ureter, it was examined closely between two fingers during this process it broke, and the surgeon became quite certain that it could not be the ureter, which is usually resistant At no time was a single vessel of any size seen nor was any bleeding point ligated

The tumour having been removed there was now a cavity extending retroperitoneally down to within two inches of the perineum This repeatedly filled with blood which oozed from all sides No attempt to find bleeding points was made, but the cavity was at once packed with ten yards of 12 inch gauze The abdomen was closed with tube drainage, and the patient left the theatre in good condition. Convalescence was a little stormy and the patient suffered from some distension. The chief difficulty was the removal of the gauze, which had two knots in it, but it was gradually taken out within 48 hours—gas-and air analgesia being used *for the removal* of each portion The wound broke down partly, but the lochia remained inoffensive The temperature was never higher than 101 5° F, and by the 18th day the wound was almost healed, the temperature and pulse rate were normal, and the patient feeling well She was discharged from hospital on the 40th day

Before the tumour was opened it was fixed in formalin. It was examined carefully 48 hours after operation, and turned out to be a kidney All renal tissue had been destroyed, and it had been converted into a pyonephrosis however, its shape and histological appearance made the diagnosis certain The strand of tissue which broke was in reality, an atrophied ureter In view of the diagnosis a self retaining catheter was kept in the bladder for a week *but there was never any discharge of urine* from the abdominal wound

The solution of the mystery was now clear The true pelvic kidney was small enough to allow spontaneous parturition until it became hydronephrotic. At the time of the first Cæsarean section the hydronephrosis collapsed during the delivery of the fœtal head—and the cyst, therefore, seemed to disappear By the time of the second Cæsarean section a pyonephrosis had formed, even then it partially collapsed during delivery of the head, and if the tumour had not been investigated before incision of the uterus it might have escaped notice for a second time

Prof HENRY BRIGGS said that an interesting feature of the case was the association of pelvic kidney and unicornuate uterus, the pelvic kidney being on the side of the missing horn —Prof. MILES PHILLIPS (Sheffield) had encountered two similar cases, in one of which the hydronephrotic kidney had been pushed up and labour had been completed by natural forces The other had been treated by Cæsarean section

The PRESIDENT gave an address on Midwifery Customs, Past and Present

---

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION —A special course in preparation for the F R C S (primary) examination will be given at the Infants Hospital, Vincent square, S W, on Mondays Wednesdays, and Fridays, from Feb 22nd to May 24th Dr Michael Kremer will take the physiology class at 5 15 P M, and Mr David Levi will take the anatomy class at 6 30 P M. An intensive course in gynæcology will be given at the Chelsea Hospital for Women from Feb 8th to 20th, while a course in medicine, surgery, and gynæcology will be given at the Royal Waterloo Hospital from Feb 22nd to March 6th A week end course in children's diseases will be given at the Princess Elizabeth of York Hospital on Feb 20th and 21st Clinical and pathological courses for M R C P candidates will be held at the National Temperance Hospital on Tuesdays and Thursdays, at 8 P M, Feb 16th to March 4th There will also be courses in chest diseases at the Brompton Hospital (5 P M, twice weekly Feb 22nd to March 20th), in heart and lung diseases, Royal Chest Hospital (on Mondays, Wednesdays, and Fridays at 8 P M March 1st to 20th), in neurology at the West End Hospital for Nervous Diseases (every afternoon, March 8th to 20th)

REVIEWS AND NOTICES OF BOOKS

Surgical Note-taking

Second edition By CHARLES F M SAINT C.B E M D M.S F R.C S Eng Professor of Surgery University of Cape Town. London: H K. Lewis and Co Ltd. 1937 Pp 91 3s

THE ability to write concise and pertinent notes on clinical cases is a fair criterion of a sound surgical training Such an accomplishment is attained mainly by working out an original system of note taking from individual experience but systems devised by others may be useful either by providing a standard of comparison and a fund from which to draw ideas, or (less desirably) by being adopted in toto Mr Saint offers to surgical dressers and clerks commencing clinical studies a system which may be used in any of these ways according to taste. After some observations on surgical dressing he briefly discusses the taking of notes in general, and then elaborates a series of schemes for taking notes on various types of cases such as injuries appendicitis diseases of the tongue each illustrated by an example The schemes on the whole are clear and complete; they contain many useful points but some are perhaps too detailed Those for abdominal emergencies and fractures are the best. There are one or two omissions of some importance in the case of head injuries no place is given to the taking of a statement by an eye witness and in the article on jaundice there is no mention of the urine

The book should be of value not only to the beginners for whom it is written but also to those about to take their qualifying examinations who will find in it a quick and convenient way to remind themselves of the points to be kept before them when examining their clinical cases

Elementary Pathology

An Introduction to the Process of Disease By KEITH S THOMPSON Pathologist Selly Oak Hospital Birmingham; formerly Lecturer in the Department of Pathology University of Birmingham and Pathologist Queen's Hospital Birmingham London: H K Lewis and Co Ltd 1936 Pp 74 10s 6d.

IN the course of teaching Dr Thompson has realised that the conventional system of note-taking during lectures leaves much to be desired The notes taken are frequently incomplete and sometimes even inaccurate whilst the time devoted to writing would often have been much better employed simply listening to the lecture Yet notes or their equivalent cannot be entirely abandoned The student in his fourth year is faced with a subject which is entirely new to him and of which he does not even understand the elementary nomenclature he feels the need of notes even if it is little more than a dictionary of terms Realising this difficulty Dr Thompson has endeavoured to overcome it by producing a book which is virtually an ideal set of notes It is interleaved with blank pages for further points or illustrative examples In its lay out the book covers the field of general pathology in a conventional manner and it could be easily adapted to meet any ordinary course of pathological lectures

The thirty two figures with which the book is illustrated deserve mention They mostly consist of full quarto pages showing a large field under low magnification This method gives the reader an excellent idea of the general architecture of the lesion The reproduction too is excellent but in one or two cases the choice of subject might have been better—e g to illustrate nutritional diseases of bone by rickets rather than by scurvy In the text there is a tendency to sacrifice strict accuracy to simplicity of expression This is seen in such statements as macrophages do not touch bacteria or that benign tumours are of normal structure but overgrown The processes of inflammation are considered too much as a conscious effort on the part of the body These are minor points which do not seriously detract from the value of the volume as an introduction

History of Chinese Medicine

Second edition By Dr K C WONG late Lecturer on Medical History National Central University; and Dr WU LIEN TEH M D Camb Director National Quarantine Service National Quarantine Service, Shanghai. 1936 Pp 906 £1 10s

THE first edition of this voluminous book was reviewed at length in our columns on its appearance four years ago (vide THE LANCET 1932 2 1337) and the general scheme remains the same but the contents have been subjected to close revision This has been a heavy task as the whole range of Chinese medical history is covered by the indefatigable authors—i.e a period of over 4600 years

The new edition like its predecessor is divided into two parts: for the first which is mainly historical Dr Chimin Wong is responsible while the second part is from the pen of Dr Wu Lien Teh The first part is divided into a legendary period (2697–1122 B C) a historical golden period (1120–960) and a mediæval period covering the next 1000 years This section has been largely rewritten as well as expanded the interesting chapters on the decline of native practice and on the struggle between the new and old forces being entirely new Such authentic records as are extant concerning Chinese medicine were studied and collated for the production of the original issue, and apart from some weeding out we have them again in this edition but the elaborate nature of Dr Wong's studies is easier to follow now that the evolution and development of the indigenous art is described in fuller shape But in the second part which treats of the introduction and progress of modern medicine we have a complete revision of the previous material whilst the events of the last eight years are described in a separate section recording the consolidation of medical work under Government auspices

Dr Lien Teh depicts the salient features of progress introduced by the early Catholic missionaries and finds that developments throughout the seventeenth and eighteenth centuries were largely due to their influence He then in considerable detail deals with the later work of the Protestant missionaries in the nineteenth century and shows how toward the end of the Manchurian dynasty a gradual adoption of European methods became systematised A full chronological table affixed to the second part enables us to ascertain at a glance the practical directions in which advances have been made and indicates the trying conditions under which progress has had to take place For example in an attack by the

Japanese Army by aerial and naval forces upon districts near Shanghai, there resulted the destruction of many medical institutions and the killing and wounding of thousands of civilians Excellent relief work was started by *foreign* medical institutions, and new hospitals were opened to deal with the situation Then came the widespread cholera epidemic which marked the end of 1932, while in that year and in the following year there were epidemics of cholera and small pox, and finally, serious outbreaks of plague in several districts These disastrous occurrences, according to Dr Lien Teh, caused no set-back to medical activities, but, on the contrary, they stimulated the Chinese to greater exertions, and the record of recent work up till the present day is one of great performance A national bureau for the control of narcotic drugs has been established, hospitals for drug addicts have been started, a midwifery school has been opened at Hankow, and similar schools have been established at other centres, a national quarantine service has taken over the Canton and Swatow stations—and many other examples of practical progress in the last three years might be cited

Dr Wu Lien Teh and Dr Wong deserve the highest credit for bringing the story of medicine in China up to date , it has been a task requiring great industry and discrimination, and the result of their labours should be of real value to their country by enhancing its scientific position

Manual of Practical Anatomy

By THOMAS WALMSLEY, Professor of Anatomy in the Queen's University of Belfast Part III the Head and Neck London Longmans, Green and Co , Ltd *1936 Pp 357 12s 6d*

THIS is a new edition of the third part of a manual which made its appearance some fourteen years ago, and had a second issue ten years later The present edition shows an increase in size resulting from the introduction of "fuller descriptions of the examination of the living body and stressing the parts which are important in clinical practice" This attempt on the part of the author to meet some of the criticism of anatomical teaching to medical students is praiseworthy, and he is to be complimented on the way in which he has carried out his intentions It is his bad fortune that he cannot correct the clinical ignorance which is at the bottom of much of the criticism This issue is a worthy successor and companion to those parts which have already appeared and have established their position among the practical manuals of anatomy

Recreational Therapy for the Mentally Ill

By JOHN EISELE DAVIS, B.A , M.A , *in collaboration* with WILLIAM RUSH DUNTON, Jr, M D London William Heinemann Ltd 1936 Pp 206 15s

THE aim of this valuable work is to offer a systematic basis and procedure for forms of treatment that are now often neglected or used haphazard The competence of the authors is beyond question —one a physician foremost in this field, the other a physical director at Perry Point, Maryland, with an unrivalled experience acquired in the treatment of ex Service 'veterans" The untiring therapeutic effort which is characteristic of American psychiatry is very plain in this practical handbook, theory is expounded in it too, but for the most part the book is concerned with the actual procedures and working problems There could scarcely be a better corrective for the belief that apart from psychotherapy there is no active treatment for mental disorder The authors define *recreational* therapy as any free, voluntary, and expressive activity, whether motor, sensory, or mental, which is vitalised by the expansive play spirit, sustained by deep rooted pleasurable attitudes and evoked by wholesome emotional release, it is prescribed by the physician, to whom the trained recreational and occupational therapists are technical assistants and advisers In the discussion of general principles and classification, as well as in the description of actual treatment, tests, objectives, and schedules for training personnel, the authors avoid the temptation to elaborate or digress so that readers who make allowance for the novelty of the subject, and the somewhat different conditions in the United States from those prevailing here, will find this work very serviceable

Manual of Blood Morphology

By LYDIA SCHUDEL Leipzig Georg Thieme 1936 Pp 45 R M 6 80

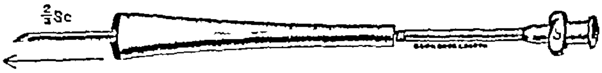
THE writer of this little manual is senior technician in Prof Naegeli's laboratory at Zurich. The technique of making platelet counts, of making cover slip preparations, and of staining them by the May Grünwald technique is described There are thirteen good colour plates illustrating the development of the blood cells and the characteristic picture found in different blood disorders No reference is made to any view concerning blood-cell origins except that taught by Prof Naegeli, which is by no means universally accepted The letterpress is in German, English, and French The book has value for the hæmatologist, but is perhaps over dogmatic for the student

NEW INVENTIONS

A NEW INSTRUMENT FOR DRAINING QUINSIES

I HAVE used on numerous occasions the following method of draining quinsies with a syringe and an adjustable guarded needle I have found it simple, practically painless, and much less alarming to the patient than the usual incision with a guarded scalpel, and it gives immediate relief

The needle is of stainless steel, 4½ in long and 1 6 mm in diameter, with an adjustable guard The needle can be fixed to an ordinary Record syringe I prefer to use a 2 c cm syringe with ring grips similar to the one used for hæmorrhoid injection



The patient is placed in a sitting position in a good light and the needle is inserted into the most dependant part of the abscess to aspirate the pus

The needle was made for me by Messrs Down Bros , Ltd., 22A, Cavendish square, W 1

LONDON: SATURDAY JANUARY 30 1937

RHEUMATOID ARTHRITIS A MOVE ON

In an address to the Institute of Hygiene last spring Dr Fortescue Fox recalled his experience when he left a house appointment at the London Hospital for a rheumatic spa in the north of Scotland and was astonished to find that many of the victims of arthritis were young women and girls As parish medical officer he was soon led to associate this painful and terribly crippling disease with residence in ill lighted crofters cottages and bothies It was actually twenty five years earlier than this that Alfred Garrod had accurately described the disease and given it the name of rheumatoid arthritis The differentiation between it and osteo arthritis was clearly defined by Sir William Hale-White and others and in all countries the belief has been gaining ground that in the rheumatoid arthritis of the young we are dealing with a specific infective disease Its rapid onset especially in adolescents with profound constitutional disturbance and destruction of tissues all point to a special or specific poison probably allied to although distinct from the rheumatic fever which invades a different set of tissues and often attacks the heart muscle But in spite of the growth of knowledge for most of these decades as Dr Ralph Pemberton once remarked this disease has been regarded with relative indifference by the medical profession and to this reason Lord Horder has no doubt rightly ascribed the fact that the treatment offered has been all manner of pseudo-science It was undoubtedly the reports made to the Ministry of Health by Dr Alison Glover in 1924 and 1928 that first opened medical eyes to the general importance of this form of rheumatoid arthritis in women and to its devastating economic results At ages between 25 to 34 years it is known that six times as many insured women as insured men are invalided from work and these figures of course do not include the delicate girls who are unable to work at all nor the housewives occupied at home There is an unhappy predilection of the disease for northern climates such as our own and some continental writers have called it the British arthritis And it is now all too clear that it is the younger women of child bearing age who are the main sufferers and that the treatment which is at present available does not rescue them from the steady progression of the disease to a state of more or less complete crippledom

It may be that we have to deal here with a disease whose progress on a certain kind of soil is inevitable or which is little amenable to remedies of any kind, and as long as the therapeutic armoury includes only baths and potions there may be no more success than some relief of the most prominent symptoms But those who have not forgotten the story of tuberculosis may recall that it was not until the symptomatic treatment gave place to a direct attack on improving the bodily resistance that hope first began to dawn It was in a relatively damp and sunless valley of the Black Forest that Otto Walther demonstrated to an incredulous world what could be done by hardening the body and increasing its natural resources against the onslaught of tubercle No one can claim for Nordrach a monopoly of climatic advantage or of clinical knowledge but it is a fact that from that venture of faith arose the proselytes who initiated the modern campaign against tuberculosis Dr Fox would have us do something of the same kind for rheumatoid arthritis In a postscript to his republished and extended lecture[1] he urges that special provision should be made for the main sufferers from rheumatoid arthritis in the form of Rest Houses. These young women are anæmic feeble languid always more or less in pain easily tired easily chilled their joints inflamed their muscles rapidly wasting They need he feels sure a prolonged special rest cure Such a Rest House would provide a combination of curative methods within its own bounds adequate physical treatment would be available, but only as an adjuvant to the fundamental period of three to six months rest under medical supervision

The direction of such a Rest House would give opportunity for investigating the disturbances of function which recent observers believe to be at the root of rheumatoid disease Here too would be place for a systematic study of body heat and of the skin and circulation with especial reference to the effects of cold for once these patients can be brought to a condition in which they again respond to the normal stimuli of our winter and spring climate half the battle would be won Dr Fox himself attaches value to the use of pure sulphur waters in the treatment and such waters are not available nearer than Wales Ireland or the north of Scotland But the practical value of an object lesson is much diminished by remoteness and we have an impression that his suggestion of Southend-on-Sea as a locality for such a Rest House is a wise one The climate there is suitable for treatment at all seasons of the year and the estuary mud unattractive as it may be in other respects makes excellent soothing baths In the Thames basin too it should be easy to secure the sympathetic interest of public-spirited people prepared to make the venture a success The proposal is not of course unique If Prof Davidson has his way—as our Scottish correspondent reported last week—something on similar lines might come into being in Aberdeen

THE IMMUNISING ANTIGENS OF BACTERIA

FROM the beginnings of bacteriology attempts were made to determine the cell-constituents of pathogenic bacteria The early work was hampered, not so much by inadequate chemical or bacteriological technique, as by lack of a definite objective By suitable treatment of large quantities of dead bacteria a number of more or less definite chemical substances were obtained , but their interest was chiefly intrinsic, and there was little to indicate which of them gave rise to morbid effects With the realisation that bacterial species are not necessarily fixed but undergo spontaneous or induced changes in their properties, chemical analysis had a definite question to answer What, for example, did PASTEUR's "attenuated" anthrax bacillus lack that endowed the natural anthrax bacillus with its virulence ? The occurrence of variants of a bacterial species morphologically different from their parents presented a related problem—the chemical constitution of the particular anatomical feature present in one form and not in the other There are few easily observed morphological changes in bacteria, but they include the loss or acquisition of a capsule, and the loss of flagella The capsulated pneumococcus was the first bacterium to be analysed in detail by chemical methods This coccus can occur in a non-capsulated form which is relatively avirulent, and by comparative analyses of the two forms the capsular substance was found to be a complex carbohydrate, the now familiar specific polysaccharide Each of the virulent pneumococcal "types" differs from the other types by reason of the differing chemical structure of, among other things, these polysaccharides , and to a certain extent the behaviour of the pneumococcus in the host can be described in terms of the specific polysaccharide substance There were, however, certain discrepancies between the properties of the polysaccharides isolated and those of similar substances present in the body fluids of the pneumococcus infected host It has lately been demonstrated[1] that the relatively brutal chemical procedures to which the pneumococci were subjected during chemical fractionation removed from the polysaccharide molecule the acetyl groups, leaving a substance still capable of reacting with antipneumococcal sera, and still determining the type-specificity of the organism Acetylation of this substance confers upon it important immunising properties, and it appears that the polysaccharide is present in the acetylated form in the pneumococcus The serological study of the de acetylated polysaccharide has been particularly fruitful, but our understanding of antipneumococcal immunity was certainly delayed because the criterion of importance adopted for the isolated substances was primarily an in-vitro serological one

Flagellated bacteria (the so called "H" forms) of the colon typhoid group exemplify the other main morphological variation, often throwing variants without flagella (the so called "O" forms) The flagella contain powerful antigens responsible for making a patient's serum positive in a Widal test, but they play a minor part only in producing disease and in stimulating immunity The O antigens, in the body of the bacteria, are of prime immunological importance Like the capsular antigens of the pneumococcus, they may be lost by the bacilli in certain circumstances, and the resulting variants are feebly virulent and poor in immunising power The adequacy of the virulent O form for the manufacture of effective vaccines was questioned by FELIX,[2] who described a new serological variant in freshly isolated, living typhoid bacilli The variants are more virulent and better immunising agents than the accepted typhoid strains, and FELIX named the hypothetical substance responsible for their peculiar properties the "Vi," or Virulence, antigen This antigen is destroyed by mild heating and by the action of certain chemical preservatives used in the manufacture of vaccines Antisera produced by horses immunised with a Vi strain are claimed by FELIX and his co workers to be effective agents in the treatment of enteric fever
